Preface

to the Second Edition

The first edition of **TIME-SAVER STANDARDS FOR BUILDING TYPES** was a unique and significant publication. It established for the first time a comprehensive source of reference material dealing with the functional analysis and standards of all major types of buildings. It contained in a single source an extensive amount of essential planning data for the architectural designer and related professionals. This was accomplished by contributions from many individuals and by researching and consolidating a wide range of literature. As much as possible, the criteria were presented in graphic form for easier reference and use. In a span of a few short years, the first edition has established itself as a useful and popular reference source to both professionals and students. In order to maintain its effectiveness and meet this need, the book requires periodic review and revision to incorporate new developments and thinking. As a result, the second edition has been published. The new edition has been expanded by over two hundred pages and approximately twenty-five percent of the original book has been revised. Obsolete pages have been eliminated and more current materials have been added. Also, several new building types have been included.

The authors wish to emphasize to the user of this handbook that the material presented is primarily offered to give basic or general data for a particular building type. This material is not intended to give definitive schematics, rigid formulas, or final design solutions that will automatically provide the solution to the particular design problem at hand. Rather, these standards and criteria should be the starting point for further analysis, study, and review of the functional relationships of each building type. Primarily, the material in this handbook is intended to be used by the architect, designer, student, or related design professionals in the following manner:

1. to assist in developing building programs and establishing preliminary space allocations.
2. to analyze specific client needs and to quantify them
3. to study general and specific functional relationships
4. to assist in the preparations of preliminary architectural designs

The authors strongly believe in the principle that "form follows function" and that before a building can succeed aesthetically it must perform its function efficiently. All the material presented in this handbook deals with the function of a building rather than its form. There is absolutely no attempt to dictate or even suggest aesthetic or definitive design solutions to any

building type. The architectural designer must have complete freedom to exercise his or her creative abilities. With the handbook's solid functional basis, this goal can be achieved more successfully.

JOSEPH De CHIARA

Preface

to the First Edition

TIME-SAVER STANDARDS FOR BUILDING TYPES is a natural outgrowth of the present fourth edition of *Time-Saver Standards, A Handbook of Architectural Design Data*. Over the years, as *Time-Saver Standards* became more popular and comprehensive, it also became larger in size and more cumbersome to use. In addition to containing architectural design data, the fourth edition also had some design material dealing with specific types of buildings. When the book was ready for a fifth revision, it became apparent that changes had to be made in the content and format of the book. In order to be able to include new design data in a comprehensive manner, it was decided to remove the material dealing with building types from the fifth edition and use this material as a core for the new book: *Time-Saver Standards for Building Types*. The original material has been revised, greatly expanded, and reorganized to cover all of the major building types. The result has been a completely new handbook for the architectural profession. It evolved from and follows the tradition of the first four editions of *Time-Saver Standards*. *Time-Saver Standards for Building Types* and *Time-Saver Standards for Architectural Design Data*, 5th edition, are closely related but, in fact, are separate and independent books.

Time-Saver Standards for Building Types is intended primarily to meet the needs of those who are involved in the conceiving, planning, programming, or design of buildings. It is intended to give basic design criteria for each major type of building. It will give those unfamiliar with a specific type of building a talking or working knowledge of its functions, organization, and major components.

This material is intended to act as a guide or reference point from which the specific design solutions can be established. Absolutely no attempt is made in this book to present the final design solution for any building type, nor does it try to establish or influence the final aesthetic expression of the building. It is hoped that the designer or architect, by having at his disposal the widest range of information concerning a building type, will be able to design more functional, more meaningful, and more exciting buildings.

The editors wish to take this opportunity to express their gratitude and sincere thanks to the many individuals, architects, libraries, and many varied organizations who have generously contributed their expertise to this new creation, *Time-Saver Standards for Building Types*.

DIMENSIONS OF THE HUMAN FIGURE

DIMENSIONS OF ADULTS

The dimensions and clearances shown for the average adult (Fig. 2) represent minimum requirements for use in planning building layouts and furnishings. If possible, clearances should be increased to allow comfortable accommodations for persons larger than average. The height of table-tops shown on the next page is 2 ft 5 in; some authorities prefer 2 ft 6 in, or sometimes 2 ft 6½ in.

Since doorways and passageways must normally be dimensioned to permit the movement

of furniture, they should seldom be designed merely on the needs of the average adult. (See section of this book relating to furniture sizes.)

DIMENSIONS OF CHILDREN

Children do not have the same physical proportions as adults, especially during their early years, and their heights vary greatly, but their space requirements can be approximated from the following table and from Fig. 1. (For heights of children's furniture and equipment, see section on "Schools.")

Average Height of Children

Age	Height, in	Age	Height, in
5	44	11	56
6	46	12	58
7	48	13	60
8	50	14	62
9	52	15	64
10	54	16	66

Fig. 2 Dimensions and clearances for adults. Source: "Time-Saver Standards," 1st ed., F. W. Dodge Corp., New York, 1946.

DIMENSIONS OF THE HUMAN FIGURE

Fig. 2 (cont.)

LIVING AREAS

Planning Considerations

- Through traffic should be separated from activity centers.
- Openings should be located so as to give enough wall space for various furniture arrangements.
- Convenient access should be provided to doors, windows, electric outlets, thermostats, and supply grills.

Furniture Clearances

To assure adequate space for convenient use of furniture in the living area, not less than the following clearances should be observed.

- 60 in between facing seating
- 24 in where circulation occurs between furniture
- 30 in for use of desk
- 36 in for main traffic
- 60 in between television set and seating

Seating arranged around a 10-ft diameter circle (Fig. 1) makes a comfortable grouping for conversation. Figure 2 indicates clearances, circulation, and conversation areas.

LIVING ROOMS

FURNITURE

GENERAL

Typical furniture-group units

While the typical furniture arrangements presented in the following pages by no means cover the entire range of possibilities, they do cover the fundamental uses to which living, dining, and sleeping spaces are put. From the suggested schemes furniture arrangements can be developed to suit any particular problem or set of problems with which a designer may be confronted.

Furniture sizes may vary slightly; those indicated are the averages commonly met with in upper middle-class homes, and are little affected by changes in style or similar matters of individual preference.

Specific space allowances

In studying furniture groupings, it becomes obvious that certain clearances are required. Spaces, lanes, or paths of different types develop naturally between furniture-group units. Minimum distances for comfort have been established by numerous planners. These, and in some cases, maximum distances based upon requirements for human intercourse, have been incorporated in the diagrams. A listing of those generally applicable to all rooms follows:

1. *Single passage* (not a traffic lane) between low objects, such as a sofa and coffee table: 18 in. is the minimum.
2. *Single passage* (not a traffic lane)

between tall objects, hip height or over: 2 ft to 2 ft 6 in. is the minimum.

3. *General traffic lane:* 3 ft 4 in. is the practical minimum. As rooms increase in size, this minimum increases, in order to preserve the space scale of the room. The traffic lane between an entrance door and a major group unit is preferably generous in width. It is desirable to place doors so that the central portions of rooms do not become major traffic ways between different parts of the house.

4. *Seating areas, confined* (for instance, between a desk and a wall): 3 ft is a minimum tolerance, which permits one person to pass back of an occupied chair. This minimum does not constitute a major traffic lane.

LIVING ROOM

Typical furniture groups in the living room are as follows:

1. *Primary conversation group:* chairs and sofa normally grouped around the fireplace
2. *Secondary conversation group:* chairs and love seat at end of room or in corner
3. *Reading group or groups:* chair, ottoman, lamp, table
4. *Writing or study group:* desk, lamp, one or two chairs, bookcases
5. *Music group:* piano, bench, storage space

6. *Game group:* game table and four chairs

7. *Television group:* television set and seating for several people

According to the price of a house and the cubage allotted to the living room, two or three or all of the furniture-group units may be included. The fireplace is so closely associated with living room furniture that it has been included in all schemes.

Clearances

Traffic tolerances in living rooms are important, since numbers of people use the room, and narrow lanes between furniture-group units are uncomfortable. An adequate traffic lane between the main entrance and the major seating group is 3 ft 4 in. wide; 4 ft 6 in. is preferred. The minimum clearance between facing pieces of furniture in a fireplace group is 4 ft 8 in. for a fireplace 3 ft wide. For every inch added to the size of the fireplace, 1 in. is added to the minimum clearance space.

If a wide sofa is placed directly opposite the fireplace, this group is often spread. A 6-ft tolerance is usually considered the maximum because it is difficult to carry on a conversation over a greater distance.

A considerable flexibility in location of doors and windows is possible, and all wall pieces can be shifted. Doors flanking a fireplace are to be avoided in order that the furniture group may be concentrated around the fireplace opening.

FURNITURE ARRANGEMENTS

1. In all living rooms shown, main conversation group centered about fireplace is dark gray. Bay or picture windows may be used as focal points, instead of fireplaces.

2. Clearance between low coffee table (23) and easy chairs (6) ought to be maintained at 3'-4" even though table is low, because the aisle here constitutes a major traffic way.

3. For larger families, or for those who entertain often, seating for 7 to 8 persons in the primary group is a reasonable design limitation. Off-center location of game group provides for a corner entrance door.

4. Minimum length for a room which must contain a baby grand piano is approximately 20'. If minimum clearances of 1' between piano and wall, and 3' between desk (15) and wall, are to be maintained, room length must be increased.

5. If sofa opposite fireplace is omitted, primary group can be brought closer together. In schemes 1 to 4, note that wide groups permit conversation without twisting to see speakers seated on sofa; here this restriction is removed.

6. Here, presumably, doors at ends of room indicate use of one side of room as a traffic route. Primary furniture is grouped closely about fireplace; wall pieces are all that can be used on opposite side.

FURNITURE ARRANGEMENTS

7. Grouping for door locations at both ends of room; ideally, 1-ft clearance is desirable between piano and wall. Chairs (6) are smaller than those previously listed, 2'-6" x 3'-0".

8. If living room has a "dead end" (no doors), primary unit may be spread to include entire end of room. Inclusion of music or game group would demand more area.

9. Primary group shown is one of most popular arrangements. Unit placing suggests entrance at left end. Secondary conversation unit often becomes music or game group.

10. Writing or study group at left, music or game group at right, and center primary group, need minimum passages only when room is narrow.

11. Ten persons can be comfortably seated in this type of arrangement, in which primary and secondary conversation groupings almost merge into one.

12. Arrangement designed to permit door locations on side walls rather than ends. Angled chairs (6) are small size noted in Fig. 7, and often used in other arrangements.

FURNITURE ARRANGEMENTS

13. Previous diagrams have shown schemes arranged symmetrically about centered fireplaces; on this and the following page are schemes for cases when foci cannot be centered.

15. If primary, music, and game groups are all to be contained in a small area, one must be curtailed. Here game group consists of table and only two chairs.

17. Two smaller upholstered chairs (6), each 2'-6" x 3'-0" might be accommodated at the right of the fireplace in this room with only a slight increase in room width.

14. Off-center rooms often divide naturally into two parts: primary group, and other groups combined. Clearance no greater than 2' will not accommodate a major traffic lane.

16. In this case the primary conversation group is curtailed to permit inclusion of a grand piano; use of corner bench for game group may result in some loss of comfort.

18. In a room with only one door the minimum traffic lane of 3'-4" needs to be increased to at least 4'-10", which will accommodate two persons side by side, without crowding.

FURNITURE ARRANGEMENTS

19. Another example of wide entrance lanes. Placement of doors so that at least 10" is allowed between room corners and door trim will permit installation of "built-in" bookcases.

21. Notice that a game-table group occupies almost the same floor area as a baby grand piano. Placement at an angle is intended for informal rooms.

23. Fireplace chairs set 3'-6" back from center line of fireplace permit occupants to gaze at the fire comfortably. General traffic cannot be accommodated in a 2-ft lane.

20. Several doors may be accommodated with this type of furniture-group unit arrangement. A traffic lane is assumed to exist at the left end of the room.

22. Larger rooms may contain four or more furniture-group units; it may be desirable to increase clearances. Use of chairs set at angles requires increased areas.

24. By using love seats instead of pairs of chairs at sides of fireplace, considerable space can be saved even though seats are not placed the minimum distance apart.

FURNITURE ARRANGEMENTS

25. In rooms with fireplaces in end walls, as in the schemes immediately preceding, furniture arrangements often fall naturally into two distinct groups.

26. One of the two groups may be adapted for dining, eliminating need for a separate dining room. Minimum clearance around dining table should be 3'-0".

27. In this scheme, by placing the sofa on the long axis opposite the fireplace, furniture is held together as a single unit. There are two obvious positions for an entrance door. It is possible to back the sofa against a group of windows.

28. Backing the primary-group furniture against walls eliminates passage behind them and reduces room width to a minimum.

29. Here the left side and end opposite the fireplace are available for doors. Piano should, if possible, be placed against an inside wall.

30. Placing the sofa against one side of the room tends to open up the primary group—in effect, to merge with it the secondary conversation-group furniture.

FURNITURE ARRANGEMENTS

31. The entire area may be treated as a single unit, all furniture being brought into the principal group.

32. Here the placing of the desk group (14) allies it closely with the fireplace unit. Four units are included.

33. By interchanging the positions of the fireplace furniture in Fig. 32, a grand piano can be accommodated.

34. Completely symmetrical arrangement in comparatively small space; music group might replace items 14 and 25.

35. Type of sofa shown is becoming increasingly popular. Chairs (6) may be units which can be added to sofa, if desired.

36. "Unit" types of sofas are particularly suited to corner groupings. Scheme shown contains three group units.

LIVING ROOM—FURNITURE SIZES AND CLEARANCES

SPACE in the small house for general living activities must often serve a wide variety of functions. Thus, furniture can add greatly to the usefulness of living area if it is adaptable in type and size to a number of different purposes.

Accompanying data give a working basis for providing sufficient space for general living activities. Dimensional information includes only a few of many available sizes and types of furniture. Dimensions of groups refer to clearances necessary for comfortable and convenient use.

Necessary planning considerations include: provision of adequate floor and wall space for furniture groupings; segregation of trafficways from centers of activities; ease of access; and a maximum of flexibility.

Doors in constant use should be placed so that traffic between them will not interfere with furniture groups.

Flexibility implies the varying uses to which space may be put. The lounging group at the right, for instance, requires approximately the same floor space as the card-playing group; the sofa, below, may be a convertible bed. Thus, functions of other areas—such as recreation, sleeping, dining and even storage—may be applicable equally to living rooms.

Sofa Sizes (B):
2'-8" to 3'-6" deep
6'-0" to 7'-2" long

Love Seats:
2'-0" to 2'-10" deep
3'-6" to 4'-6" long

End Tables (A):
10" to 1'-2" wide
1'-6" to 3'-0" long

Occasional Tables (C):
2'-0" to 2'-4" square, round, oval, draw-top, etc.

Card Tables:
2'-6" to 3'-0" square; folding type 1 1/2" thick folded (average)

Side Chairs:
1'-6" to 2'-0" wide
1'-6" to 1'-10" deep

Double Bed Studio Couch

Desks, Sloping Top:
3'-0" to 3'-8" wide
1'-6" to 2'-0" deep

Writing Desks:
2'-8" to 3'-6" wide
1'-6" to 2'-6" deep

Secretaries:
3'-0" to 5'-0" wide
1'-6" to 2'-8" deep

Convertible Sofa-Beds (G): 2'-9" to 3'-3" deep, 6'-2" to 6'-8" long

Living Room Tables (F): 1'-8" to 3'-0" wide, 3'-6" to 10'-0" long

Easy Chairs: Wing, 2'-4" to 2'-10" square; Club, 2'-4" to 3'-3", 3'-9" square

Book Cases (D): 2'-6" to 3'-0" wide, 10" to 12" deep

DINING AREAS

By GLENN H. BEYER AND ALEXANDER KIRA, *Housing Research Center, Cornell University*

DINING ROOM

The principal factors to be considered in planning the dining area are as follows: (1) Number of persons to be seated; (2) Space used at the table; (3) Space for chairs and for passage behind them; (4) Seating arrangement; (5) Size and type of furniture; and (6) Storage space for china, glassware, silver, and linen.

Recommended space dimensions, based on recent research, are provided below.

SIZE OF PLACE SETTING

The minimum width needed for each place setting is 21 in.; however, a width of up to 29 in. is desirable for greater freedom of movement. A 25-in. width is usually adequate; this permits chairs 19 in. wide to be placed 6 in. apart. The minimum depth for a place setting is 14½ in. These dimensions allow space for china, glassware, silver, and elbow extension (See Fig. 1).

PASSAGE BEHIND CHAIRS

The minimum space recommended for passage behind chairs is 22 in.; a satisfactory range is 22 to 25 in. If passage behind the chairs is not required, a minimum of 5 in. plus the depth of the chair must be provided for pushing back the chair when leaving the table (See Fig. 3).

Size of table

The minimum width recommended is 36 in.; a satisfactory width is 36 to 44 in.

If 25-in.-wide place settings are provided and if one person is seated at each end of the table, then minimum and recommended table lengths are as follows:

Persons	Minimum, in.	Recommended, in.
4	54	60
6	79	84
8	104	108
10	129	132
12	154	156

Table 1. Inside dimensions of drawers for storage of silverware

Adapted from *Indoor Dining Areas for Rural Homes in the Western Region, Report 118, University of Arizona Agricultural Experiment Station, Tucson (June 1955).*

Item	Width, in.	Depth, in.	Height, in.
8 each forks, knives, soup spoons; 12 teaspoons, 6 tablespoons, 4 serving pieces	11	18½	2¾
12 each forks, knives, salad forks or others, butter spreaders, soup spoons; 18 teaspoons, 6 table spoons, 3-piece carving set, 3 serving pieces	14½	20	3
12 each forks, knives, soup spoons, salad forks or butter spreaders; 24 teaspoons, 6 tablespoons, 6 serving pieces	17	19¾	2¼

Table 2. Dimensions of stacks of folded table linens

Adapted from *Storage Space Requirements for Household Textiles, A. Woolrich, M. M. White, and M. A. Richards, Agricultural Research Bulletin 62-2, U.S. Department of Agriculture, Washington, D.C. (1955). Dimensions given are front-to-back, side-to-side, and height.*

Item	Space 16 in. deep		Space 20 in. deep	
	Minimum, in.	Maximum, in.	Minimum, in.	Maximum, in.
2 large tablecloths, guest use	14x19x3	14x36x2	19x14x3	19x28x2
2 medium tablecloths, everyday use	15x19x1	13x28x1	19x10x1	18x28x1
4 small tablecloths, everyday use	14x10x3	14x28x1	10x14x3	15x14x2
3 small tablecloths, guest use	14x10x2	14x28x1	10x14x2	15x14x2
12 small napkins (2 stacks of 6)	7x10x3	7x10x3	10x 5x3	10x 9x2
12 large napkins (2 stacks of 6)	8x10x2	8x10x2	10x 6x2	10x10x1
6 place mats, everyday use	13x19x1	13x19x1	19x13x1	19x13x1
1 table pad	13x21x3	13x21x3	13x21x3	13x21x3

If no one is seated at either end of the table, the length may be reduced by approximately 4 in.

Space for total dining area

With the same conditions noted above and with an ample 42-in. space for passage on all sides of a 42-in.-wide table, required sizes are as follows:

Persons	W × L ft	Area sq ft
4	10½ × 12	126
6	10½ × 14	147
8	10½ × 16	168
10	10½ × 18	189
12	10½ × 20	210

If no one is to be seated at either end of the table, the length may be reduced by 2 ft (21 sq ft).

Storage space

Linear feet of shelf space required for medium-income families, for both moderate and liberal supplies of dishes and glassware, for everyday and guest use, is as follows:

	12-in. shelves, ft.-in.	20-in. shelves, ft
Moderate	21-0	2
Liberal	36-9	2

Drawer space for storage of silver is shown in Table 1. Space for storage of table linens is shown in Table 2.

Fig. 1. Size of place setting

Fig. 2. Passage behind chairs

Fig. 3. Leaving the table

DINING AREAS

DINING AREAS must accommodate furniture—either portable or built-in—for eating, sitting, serving and possible storage. Equipment for these dining functions may also be adapted to meet other possible requirements for this space—as studying, game-playing, etc.

Table space requirements per person are as follows: for crowded seating, 1'-10" on the table's perimeter; for comfort, 2'-0". Adequate clearances for use are indicated on diagrams.

Furniture Sizes:

Portable Tables, round (A):
2'-7" to 5'-10" diam.

Portable Tables, rectangular (C):
2'-6" to 4'-0" by 3'-6" to 8'-0";
or 2'-0" to 4'-0" square

Dining Chairs, portable:
1'-6" to 2'-0" by 1'-6" to 1'-10"

Serving Table (B):
2'-6" to 3'-6" by 1'-2" to 1'-9"

Sideboard or Buffet (B):
4'-0" to 6'-6" by 1'-5" to 2'-1"

China Cabinet (B):
2'-8" to 3'-8" by 1'-2" to 1'-9"

Furniture Clearances

To assure adequate space for convenient use of the dining area, not less than the following clearances from the edge of the dining table should be observed.

- 32 in for chairs plus access thereto
- 38 in for chairs plus access and passage
- 42 in for serving from behind chair
- 24 in for passage only
- 48 in from table to base cabinet (in dining-kitchen)

Figures 4, 5, and 6 illustrate proper clearances. Various arrangements appear on the next page.

Fig. 4 Dining room for 6-person, 3-bedroom living unit.*

(a)

Fig. 5 Dining room for 8-person, 4-bedroom living unit.*

(b)

Fig. 6 Minimum clearances for dining areas. (a) one end of table against wall; (b) serving from one end and one side of table. Source: "Housing for the Elderly Development Process," Michigan State Housing Development Authority, 1974.

* From "Manual of Acceptable Practices," Vol. 4, U.S. Department of Housing and Urban Development, 1973.

DINING AREAS

1. Minimum requires 2-ft buffet space on one side only; 3' more length is needed for extension table.

2. Typical dining-room suite, as used in East and on West Coast, requires furniture space on two sides of room.

3. Long narrow area with some waste space results when wall pieces are at ends, and end entrance is needed.

4. Solid lines indicate minimum room with corner cupboards, no wall furniture. Dotted lines indicate added space for 3' breakfast table.

5. Table-and-passage unit in one corner permits use of minimum space for multiple activities; piano may be replaced by desk, love seat, etc.

6. Spaces smaller than the usual minimum can be utilized if built-in seats are included; seating and table-service comfort are sacrificed.

7. The same set of clearances applies to the seldom used round table as to the more popular oblong table.

8. Arrangement of typical suite in larger-than-minimum space, when a screen is used at serving door.

9. Dining rooms with fireplaces have to be larger than minimum for the comfort of those seated at table.

19

COMBINED LIVING-DINING SPACES

COMBINED SPACES

Often several compatible living functions can be combined advantageously in a single room. Some of the benefits of such arrangements are that less space is used but it is used more intensively, its functions can be changed making it more flexible and serviceable space, it is adaptable to varied furniture arrangements, while visually it can be made more interesting and seem more gener-

ous than if the same functions were dispersed into separate rooms.

For adjacent spaces to be considered a combined room, the clear opening between them should permit common use of the spaces. This usually necessitates an opening of at least 8 ft. Figures 8 and 9 show combined living-dining rooms.

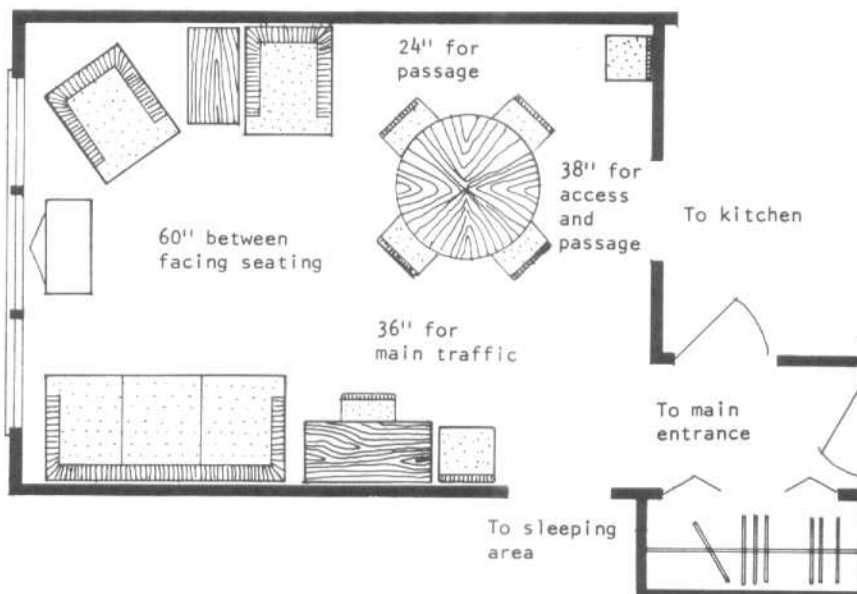

Fig. 8 Combined living-dining room.*

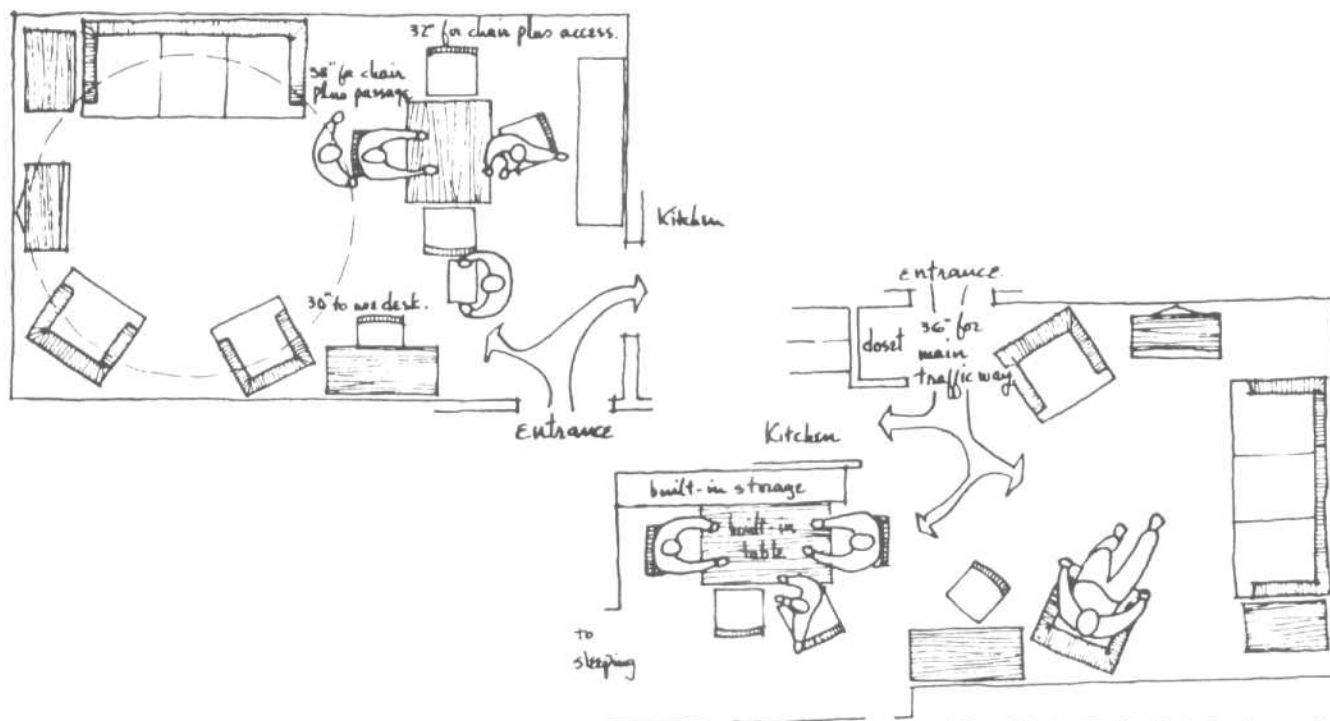

Fig. 9 Minimum clearances and circulation for combined living-dining areas.*

* From "Housing for the Elderly Development Process," Michigan State Housing Development Authority, 1974.

COMBINED DINING AREA-KITCHEN

A combination dining area-kitchen is preferred by some occupants of small houses and apartments. This arrangement minimizes housekeeping

chores and provides space which can be used as the family's day-to-day meeting place.

21" sink counter combined
with 21" range counter

Fig. 10 Combined dining area-kitchen, 2-bedroom living unit. Source: "Manual of Acceptable Practices," Vol. 4, U.S. Dept. of Housing and Urban Development, 1973.

One of the primary functions of the kitchen has been to provide a place for informal or family eating. This is different than guest or formal dining in a separate dining room or area. The informal dining generally consists of breakfast, lunch,

snacks, or just serving coffee to a neighbor. This eating area should be clearly defined as a separate functional area.

A frequent and desirable arrangement is the combined kitchen-dining area. The following

sketches (Fig. 11) show the various possible arrangements. Another arrangement is the kitchen-family room.

Fig. 11 Minimum clearances for dining area in kitchen. Source: "Housing for the Elderly Development Process," Michigan State Housing Development Authority, 1974.

BEDROOM

DIAGRAMS indicate minimum clearances that should be provided for use of the bedroom furniture shown, dimensions for which are listed below. Many types and sizes of furniture are available; but those listed are most common and can serve as a basis for bedroom design. At least 2 in should be allowed as clearance between walls and furniture; 3 in between furniture units.

Beds:

Single (C), 3'-0" to 3'-3" wide; 6'-10" long.
Twin (F), 3'-3" wide; 6'-10" long.
Three-quarter (E), 4'-0" wide; 6'-10" long
Three-quarter (B), large, 4'-2" to 4'-6" wide;
6'-10" long
Double, 4'-6" wide; 6'-10" long.
Roll-away beds, (A): 2'-0" by 5'-0" on edge, 3" clearance on all sides

Bed Tables (G):

1'-2" to 2'-0" by 1'-0" to 2'-0"

Bedroom Chairs (H):

Small, 1'-8" by 1'-8"; larger, 2'-6" to 2'-10" by 2'-8" to 3'-2"

Dressers (3-drawer) (D):

3'-0" to 4'-0" by 1'-6" to 1'-10"

Chest of Drawers (4-drawer) (D):

2'-8" to 3'-4" by 1'-6" to 1'-10"

Chaise Longue:

2'-0" to 2'-4" by 4'-0" to 5'-6"

Day Bed:

2'-9" to 3'-3" by 6'-2" to 6'-8"

Dressing Table:

1'-3" to 1'-10" by 3'-0" to 4'-2"

Double-deck bed

Roll-away bed

Large three-quarter bed

Clearance for dresser

Minimum clearances for twin-bed group

Minimum clearances for single bed and dresser group

Fig. 2 (a), (b) Primary bedroom, (c) primary bedroom without crib.*

FURNITURE CLEARANCES

To assure adequate space for convenient use of furniture in the bedroom, not less than the following clearances should be observed (Figs. 2 and 3).

42 in at one side or foot of bed for dressing
6 in between side of bed and side of dresser or chest

36 in in front of dresser, closet, and chest of drawers

24 in for major circulation path (door to closet, etc.)

22 in on one side of bed for circulation

12 in on least used side of double bed. The least-used side of a single or twin bed can

be placed against the wall except in bedrooms for the elderly (Fig. 4).

* From "Manual of Acceptable Practices," Vol. 4, U.S. Department of Housing and Urban Development, 1973.

FURNITURE ARRANGEMENTS

The location of doors and windows should permit alternate furniture arrangements.

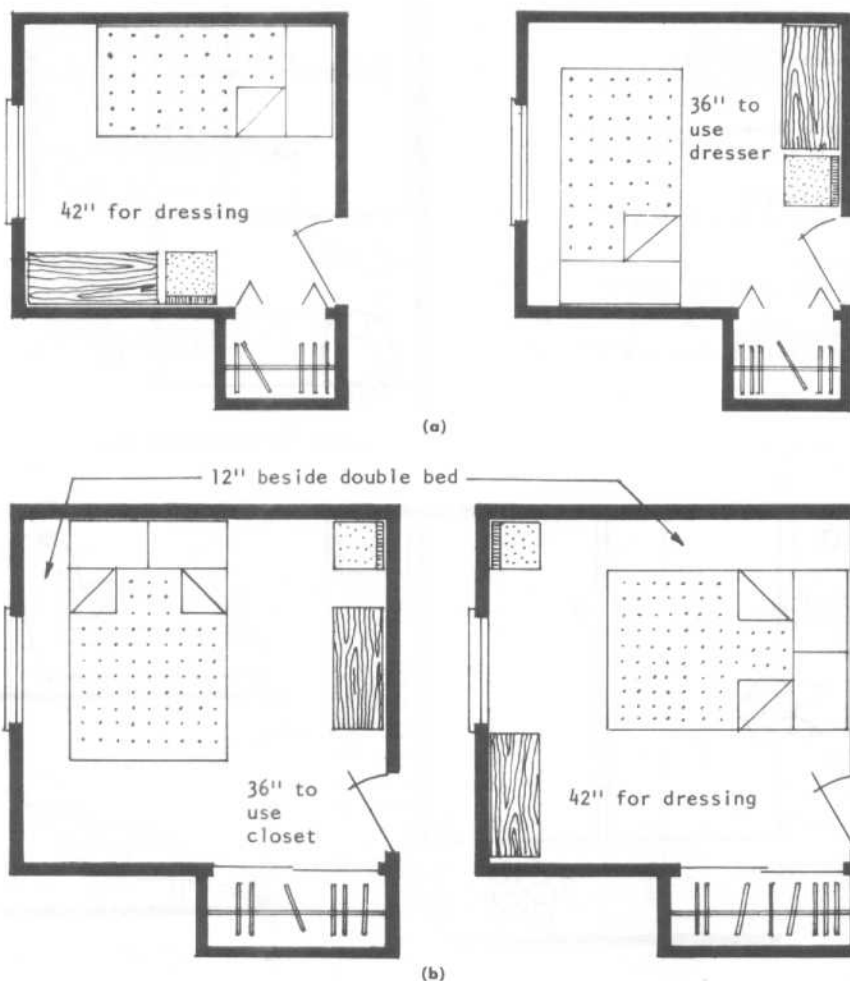

Fig. 3 (a) Single-occupancy bedroom; (b) double-occupancy bedroom.*

Fig. 4 Single-occupancy bedroom for elderly; there is a 12-in allowance to make the bed.*

Where at least two other sleeping spaces are provided, a dormitory is sometimes preferred by larger families (Fig. 5).*

* From "Manual of Acceptable Practices," Vol. 4, U.S. Department of Housing and Urban Development, 1973.

Fig. 5 Dormitory bedroom.

TYPICAL UNIT ARRANGEMENTS

1. For comfort, 2 night tables are desirable with a double bed. A minimum double-bed unit arrangement may be achieved by omitting arm chair and one side chair, and reducing to 3'-6" the traffic lane at foot of bed.

2. Use of small chairs and chest makes possible the addition of conversation or lounging furniture (2 chairs and table) to a typical suite, without increasing square footage. Use of 3-ft passages eliminates crowding.

3. Other types of arrangements beyond the minimum include addition of a chaise longue (shown dotted above), which is usually placed at an angle to walls, requires a table, and necessitates ample passages.

4. Minimum twin-bed group (2 night tables) needs 9'-6" wall.

5. Increased requirements for addition of dressing table and boudoir chair.

6. Twin beds with single night table require 8' of wall space.

7. Variations on this plan may be developed by replacing the chair between the beds with a dressing table which serves also as a night table. This would free other walls for twin chests, shown dotted.

8. Twin beds heading toward a common corner may require less space than is indicated if dressing table and boudoir chair are omitted.

COMBINED LIVING-SLEEPING AREAS

9. Single-bed unit with two night tables requires 6'-6" wall.

10. Minimum dimensions for passage both sides of bed.

11. Unusual but satisfactory arrangement or long, narrow space; if units E and F are reduced 2'-0" in length, room length may be decreased 2'-0".

12. Minimum for couch or single bed placed sideways to wall.

13. If position of chest is changed room width may be reduced 6".

14. Door-swings may require increased clearance at foot of bed.

15. Slightly more comfortable than Fig. 14, but bed making is difficult.

COMBINED SPACES

A bed alcove with natural light and ventilation and which can be screened from the living area is desirable in a 0-bedroom living unit (Figs. 1 and 2).

Fig. 1 0-Bedroom living unit.*

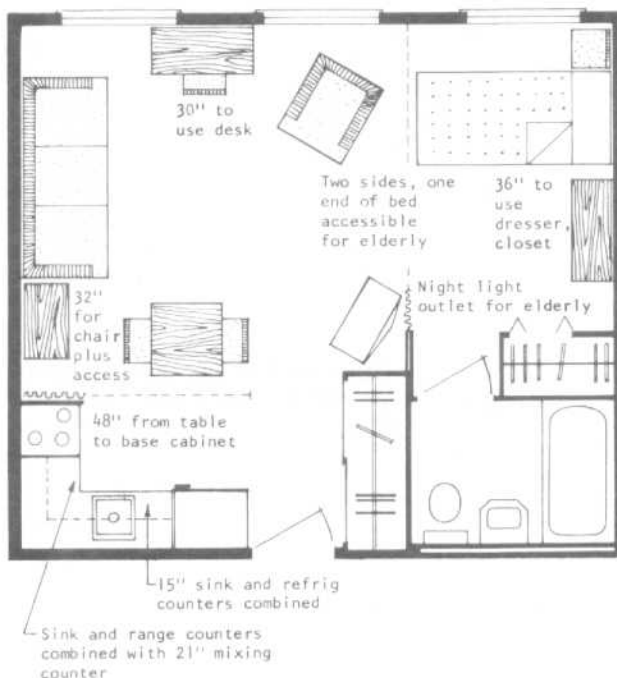

Fig. 2 0-Bedroom living unit with sleeping alcove.*

* From "Manual of Acceptable Practices," Vol. 4, U.S. Department of Housing and Urban Development, 1973.

COMBINED LIVING-SLEEPING AREAS

Fig. 3 0-Bedroom living unit for wheelchair user.*

In housing for the elderly and handicapped, the units suitable for wheelchair users often can be placed advantageously on the ground floor (Fig. 3).

Night light outlet

Omission of an easy chair is acceptable to give more space for occupant's wheelchair (Fig. 4).

Fig. 4 0-Bedroom living unit for wheelchair user.*

* From "Manual of Acceptable Practices," Vol. 4, U.S. Department of Housing and Urban Development, 1973.

By GLENN H. BEYER AND ALEXANDER KIRA, *Housing Research Center, Cornell University*

KITCHENS

The kitchen is not a specialized workroom, for it has many uses. It is used for preparation of meals, food preservation, storage of food and utensils, and also, in many cases, for eating, laundering, entertaining, and child care. In it a woman uses her own labor and also makes full use of electric power, tap water, and manufactured or bottled gas; she uses refrigerators, stoves, dishwashers, mixers, toasters, and garbage-disposal units, as well as various kinds of storage compartments and work surfaces.

Since more time and effort are frequently spent in the kitchen than in any other area of the house, careful planning is especially important. This requires careful selection of appliances and storage units and convenient arrangement of the area. Some general planning guides are as follows:

FOOD PREPARATION

Arrangement

It is important to keep the basic work area compact, even if the kitchen is of the large "living" type. Consideration should be given, however, to the possibility of more than one person working there. The arrangement will vary according to the size and shape of space available, but we should always keep in mind relationships among functions in different areas of the kitchen.

Traffic lanes

Traffic lanes through work areas should be avoided. Arrange the service entrance and access to the basement so that traffic not essential to food preparation, service, or storage can by-pass the area.

Storage

Kitchen design should be functional in the sense of minimizing reaching and stooping. Storage facilities should be no higher than a woman can reach with both feet flat on the floor. There should be sufficient space to store items so that they may be easily seen, reached, grasped, and taken down and put back without excessive strain. With proper planning, stored items can be located close to where they are first used, and unattractive items can be kept out of sight. Storage space should be sufficiently flexible to permit its adjustment to varying amounts, sizes, and kinds of food, supplies, and utensils. Shelving should be adjustable.

Counters and working surfaces

The height of counters and working surfaces should permit a comfortable working posture. The worker should be able to sit, if she wishes, while doing certain kitchen tasks, such as working at the sink. Continuous lines and surfaces permit ease of movement, and are easier to keep clean.

Servicing and replacement of appliances

Consideration should be given to ease of servicing and replacement of major appliances, especially built-in units.

Materials

Materials and finishes that minimize maintenance and cleaning should be used, and they should be sufficiently light in color to create a pleasant work atmosphere.

Lighting

Good lighting helps to prevent fatigue, as well as promoting safety and a pleasant atmosphere. Comfortable levels of light,

with a minimum of shadows, should be planned throughout the kitchen. Adequate daylight or artificial lighting makes the room more agreeable and attractive than a dark or poorly lighted room.

Ventilation

The kitchen should be well ventilated, with an exhaust fan to remove objectionable kitchen odors.

Safety

Burns, scalds, falls, and explosions should be "designed out" of the kitchen. Sharp corners, exposed handles, and control knobs on kitchen equipment should be avoided, and there should be safety catches on doors and drawers to limit the exploratory activities of young children.

Accessibility

There should be easy access to front and back doors, laundry area, telephone, and bathroom.

Decoration

Color, texture, and decoration should be used to create an atmosphere that is attractive, cheerful, and restful.

OTHER KITCHEN ACTIVITIES

Nonworking areas

Nonworking areas should be segregated from working areas. Avoid interruption of work areas by breakfast nooks, general storage closets, rest areas, and other areas not essential to normal food preparation activities.

Eating facilities

Most families want to eat some meals in the kitchen. Provision should be made for this, if possible, even if a separate dining room is also provided.

Child's play

In younger families, especially, there is likely to be one or more children who want to be near their mother. Provision should be made for a play area out from underfoot, but where adequate supervision is possible. Storage space should be provided for toys and games.

Infant care

It is a well-known fact that many kitchens are used for care of infants. If provision is not made in the bathroom for infant care and related supplies, then it should be made in the kitchen.

Grooming

Washing hands and some personal grooming frequently take place in the

Fig. 1 Vertical and horizontal limits of reach.

KITCHENS

kitchen, especially if there is not ready access to the bathroom. A mirror is desirable.

CRITICAL DIMENSIONS

The "critical dimensions" for working space are illustrated in Figs. 1-4. These

dimensions are recommended on the basis of research and do not necessarily coincide with either current practice or currently available cabinets and equipment. Width requirements for counter space, in particu-

lar, are based on research covering operations at individual work centers. Overlapping is permissible if work at adjacent centers is not being carried on simultaneously.

Fig. 2 Minimum counter-width dimensions.

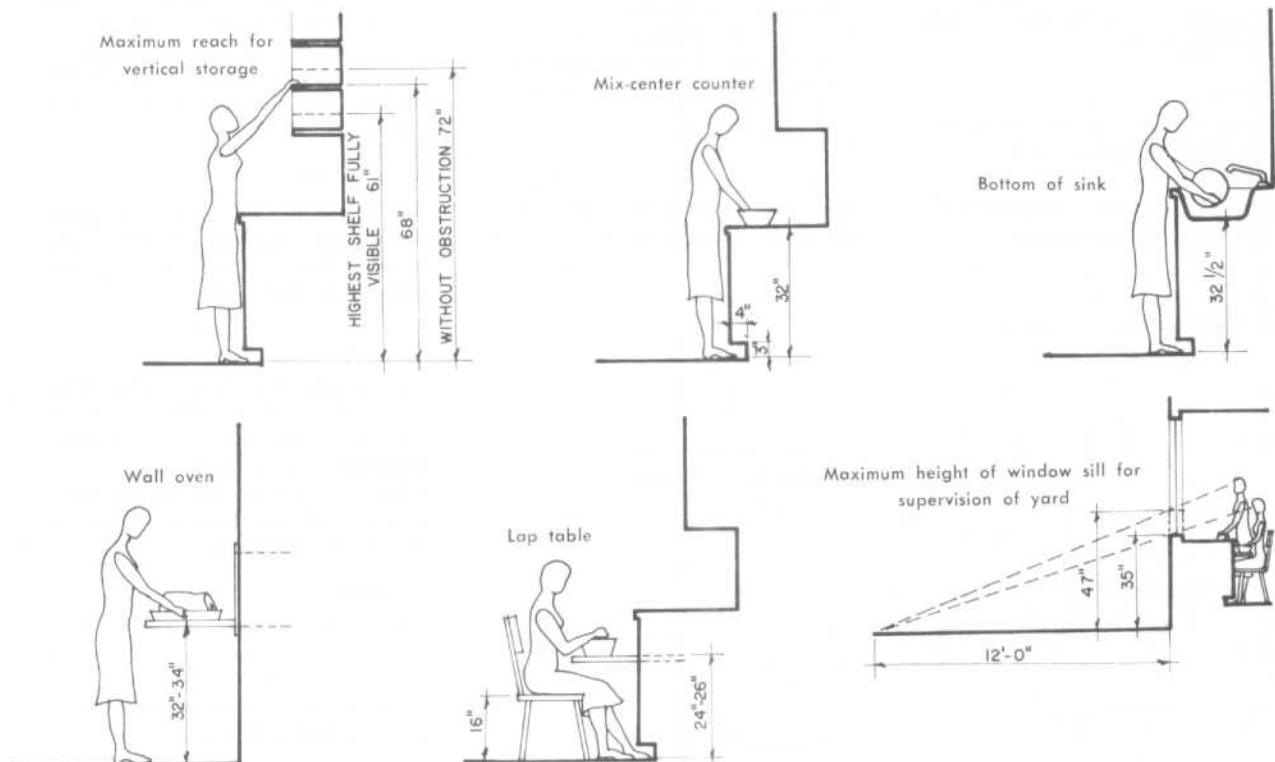

Fig. 3 Comfortable working heights.

Fig. 4 Minimum clearances—horizontal and vertical.

BASIC WORK AREAS

The work center concept, favorably supported by a great deal of research data from many sources, emphasizes the planning of the kitchen in terms of its major centers of activity. These work centers, in turn, are planned in terms of their constituent parts, their proper functions, and their ideal relationships, one to another. The actual design of the work centers will vary with the size and shape of space available in each project. Four work centers must be considered: sink, range, mix, and serve. In addition, there is the refrigerator (which functions as a closely related storage center) and the oven, if it is not an integral part of the range.

Each work center should have three components: (1) Adequate storage space for the various items used there; (2) Adequate counter space for the work to be accomplished; and (3) Necessary utilities and facilities, such as water at the sink, heat at the range, outlet and space for the mixer at the mix center, and adequate lighting at each center.

Equip each work center for the storage of utensils, supplies, and dishes according to their frequency and order of use.

Tables 1-4 list the number of items and the space dimensions required for equipment and food supplies commonly stored

Table 1. Equipment and food supplies stored at range center

Item	Number stored		Storage space per item, in.*		
	Limited	Liberal	Side to side	Front to back	Height
Equipment					
Potato masher	1	1	3½	13	4½
Knives, forks, spoons	3	3	3½	13	3
Frying pan, 10½-in.	1	1	11	17½	5½
Frying pan, 9-in.	1	2	9½	16	5
Frying pan, 6-in.	0	1	6	12	5
Pot lids	2	4	10½	10½	1
Potholders	4	8	7	7	2†
Food supplies					
Rice, 1-lb pkg.	1	1	2½	4	6½
Spaghetti, 1-lb pkg.	1	1	2½	11½	6
Coffee, 1-lb can	1	1	5½	5½	4
Oatmeal, 3-lb box	1	1	6	6	11
Macaroni, 1-lb pkg.	1	1	2	5½	9
Tea, 8-oz pkg.	1	1	2½	4½	7

*Dimension of the item (including lid, if any) plus clearance for handling.

†Provides for stack of 6 potholders.

KITCHENS

at each of the four centers. These lists represent the storage space requirements for the average family, but they may be adapted to the needs of particular families. The storage space dimensions are based on the most recent information available.

KITCHEN ARRANGEMENT

The relative location of work centers should permit a continuity of kitchen activities as follows: (1) Storage (gathering materials needed for the performance of the task); (2) Cleaning and mixing (or initial preparation); (3) Cooking; (4) Serving, or storing for future use; and (5) Cleaning up. (See Fig. 5.)

In principle, any plan that interrupts this continuity with doors, or with non-working areas or facilities, is faulty because extra steps are required every time the gap is crossed, and, consequently, convenience and working efficiency are reduced.

The actual plan may be U-shaped or L-shaped, or it may be of the corridor type.

The "U" arrangement affords the most compact work area. Frequently, however, this arrangement is impossible to achieve because of the necessity of having a door on one of the three walls. The resulting "Broken U" arrangement still permits compactness, but traffic is allowed through the area. Therefore, special consideration should be given to the arrangement of the work centers in order to minimize the effect of through traffic.

The "L" arrangement is ideally suited where space along two walls is sufficient to accommodate all of the necessary work areas. This arrangement has the advantage of concentrating the work area in one corner, thus minimizing travel, but it has the disadvantage of necessitating longer trips to the extremities of the "L."

The "Corridor" arrangement is satisfactory where doors are necessary at each end of the space. This arrangement frequently has the advantage of the parallel walls being closer together than in the typical "U," but the disadvantage of a greater distance along the corridor.

An important factor in determining the location of specific work areas within any of these over-all arrangements is frequency of use, which in Fig. 6 is expressed as the percentage of trips to and from each area.

Figures 7-9 provide floor plans illustrating some possible arrangements of the basic work centers within each of the plan types. If the space for the kitchen is already established, the number of possible satisfactory arrangements obviously will be limited. If the space is being planned,

however, greater choice of arrangements is possible. In either event, the advantage of a shorter distance between some related areas must be balanced against the resulting increase in distance between other related areas. An end-to-end alignment or a right-angle arrangement between areas of close relationship can eliminate trips and reduce the over-all travel distances. Functional relationships between key work centers are, of course, accommodated more ideally in some of the plans than others.

FHA REQUIREMENTS FOR KITCHEN STORAGE¹

Total shelf area: 50 sq ft minimum; not

¹From Minimum Property Standards for One and Two Living Units, Federal Housing Administration, Washington, D.C. (Revised, July 1959).

less than 20 sq ft in either wall or base cabinets.

Total countertop area: 11 sq ft minimum. Total drawer area: 11 sq ft minimum. (If a 39-in. range is provided, it may be counted as 4 sq ft of base cabinet shelf area and 2 sq ft of countertop area.)

Wall shelving: 74 in. maximum height.

Countertop: 38 in. maximum height, 30 in. minimum height.

Height between wall cabinets and countertop: 24 in. minimum over range and sink, 15 in. minimum elsewhere. (Shelving may be closer if it does not project beyond a line drawn from the front edge of the wall cabinet at an angle of 60 deg to the bottom of the cabinet.)

Depth of shelving: wall shelving—4 in. minimum, 18 in. maximum; base shelving—

Table 2. Equipment and food supplies stored at sink center

In addition to the items listed below, allow space for hand tools (such as can opener, small vegetable brush, paring knives, rubber plate scraper), cleaning supplies (such as soap, soap powder, cleanser, paper towels), garbage and trash containers, and possibly a stool for sitting.

EXAMPLE: MEASUREMENT OF SHELF AND COUNTERTOP AREAS

LAUNDRY ROOMS

By GLENN H. BEYER AND ALEXANDER KIRA, *Housing Research Center, Cornell University*
(including material adapted from previously published article by Larch C. Renshaw in 3rd ed. of *Time-Saver Standards*)

LAUNDRIES

Laundering includes a host of tasks—collecting and sorting dirty clothes, pretreating, washing, drying, sprinkling and ironing—all of which are tiring, for they require a great deal of stooping, lifting, and carrying. To reduce the amount of effort required, a laundry center (either separate or combined with another area) should be carefully planned. Some basic planning considerations are as follows:

Arrangement

The sequence of laundering operations should determine the planning of space and facilities and the placing of equipment.

Traffic lanes

With automatic equipment, many families now wash clothes three or four days a week. Therefore, laundering should not be done in any of the congested areas of the house. Passageways should be at least 4 ft wide. If the laundry area adjoins the kitchen, there should be a barrier of some type, at least a counter, between the two areas.

Equipment and facilities

To reduce the amount of effort required, a laundry center should have a sorting table, a heating surface (such as a hot plate), and storage facilities for soiled clothes, washing supplies, and baskets, as well as a washing machine, dryer, and ironing board; some may also have ironers. A laundry tray (usually a 14-in.-deep porcelain enamel sink) is desirable for prewashing, soaking, or starching some items.

Space

The space should be dry, heated, and well lighted, with sufficient electrical outlets, properly located. The space should be ventilated to remove moisture and odors.

Accessibility

Laundry centers today can be more conveniently located because of the compactness of automatic washers and dryers and the elimination of much of the dampness and disorder formerly associated with household washing. Although many locations are possible (such as the kitchen, bath, separate laundry room, or utility room), the laundry center should be accessible both to the work areas of the house (since frequent trips to and from them may be required during any of the laundering processes) and to outdoor summer drying areas.

FLOW OF WORK

Convenience and efficiency are achieved by placing the equipment in their natural

order of use: (1) Clothes chute (with or without bins or hampers), (2) Sorting and pretreating table or counter, (3) Washing machine, (4) Laundry tray (if available), (5) Dryer, (6) Ironing board (and ironer, if available), and (7) Standing or hanging bar and counter for ironed items. In addition, a storage closet or cabinet is necessary for cleaning supplies. In some instances, a hot plate is also needed. Some of these facilities and equipment are described in more detail below.

Clothes chute: In two-story houses, the chute is a handy device for delivering clothes from upstairs. It should empty on or near the sorting table so that the clothes will not have to be carried or handled more than necessary. It should be vertical, because curved sections are likely to cause clothes to clog the chute.

Sorting and pretreating table: Ample space should be allowed on a table or counter for sorting and dampening the clothes, and for a clothes basket, as well as space for the worker using the table. The table size required will depend upon the size of the average wash load. Research at Pennsylvania State University indicates that a table 6x2½ ft is required for a 32-lb, 4-load laundry. For pretreating, an area 20x36 in. is adequate for work and equipment (pan, brush, soap, and kettle).

Washing machine: Automatic washers and dryers permit much more convenient and compact arrangements than were possible with nonautomatic equipment. The total floor area needed is determined by the type of washer, the other equipment needed, and the space for the worker. The old-fashioned, galvanized tubs are not required with automatic equipment, but, as indicated earlier, a laundry tray is desirable. To ensure that a laundry area is both economical in use of space and convenient to work in, the dimensions shown in Fig. 4 should be followed.

Drying: The research at Pennsylvania State University revealed that 124 lin ft of line is required to hang a 4-load laundry of 32 lb.

The space requirements for different styles of dryers, and for operating them, are shown in Fig. 5. The combination washer-dryer or the stacked arrangement of washer and dryer requires less floor area than other arrangements. These dimensions are shown in Fig. 6.

Since some garments must be hung to drip-dry, a pull-out drying rod or similar arrangement should be provided, preferably above a laundry tray (or a floor drain, if the laundry is in the basement).

Ironing: An ironing board adjustable from a height of 23 to 37 in. accommodates

most women when sitting or standing to iron. The choice of either a built-in or a freestanding board depends upon personal preference. Freestanding boards should be stored where they are readily accessible. The space needed to use a hand iron at a board is shown in Fig. 2. The space needed to use an ironer, with auxiliary equipment, is shown in Fig. 3.

The storage closet should be large enough to accommodate soaps, spoons, sieves, bleaches, bluing, stain remover, starch, clothespins, and the like. If a storage cupboard 8 in. in depth is placed over an automatic washer, it should be at least 20 in. above the washer; and if 12 in. in depth, it should be 24 in. above the washer. This clearance allows for head room when using the water faucets.

SPACE ARRANGEMENTS

Laundering may be done in a room designed especially for this purpose, or in a multiuse room, designed also for food preparation, sewing, child play, and the like.

The best location, of course, is convenient to other work centers, such as the kitchen, and to the drying yard so that there will be a minimum of carrying necessary. Generally, basements are not considered desirable locations because of their inconvenience, dampness, and lack of adequate light.

Figures 7-13 provide floor plans illustrating various arrangements of basic work areas needed for the laundering process. In some of the plans shown, the space needed for laundering is treated as a separate area; in others, possible combinations with other areas are indicated.

EQUIPMENT

Figure 1 and Tables 1 and 2 provide basic dimensions of a typical automatic washer, dryer, combination washer-dryer, and ironer. These dimensions may be used for preliminary planning purposes, but final selection of equipment and detailing of working drawings should always be based on specific manufacturer's data.

Dimensions have been drawn from the current catalogs of leading manufacturers of each type of equipment. Special and nonresidential equipment are not included. Dimensions are generally given only to the nearest half inch since dimensions of new models vary slightly from year to year.

Door swings, location of vents, and the specific requirements for power, waste, and water supply should be checked against the manufacturer's data after units have been tentatively selected.

LAUNDRY ROOMS

Table 1. Dimensions for matched automatic washer and dryer

Washer and dryer may be free-standing or built into adjoining base cabinets. Some models are available without tops and splashboards for undercounter installation (the height is then 34½ in.), with both doors front-opening. Some models have sloped fronts; others may be stacked vertically, built-in.

BATHROOMS

¹Many of these suggestions are by courtesy of the American Radiator and Standard Sanitary Corporation.

Good ventilation is essential in bathrooms, both to reduce humidity and to dispel odors. If a window is relied upon as the sole means of ventilation, care should be taken in its selection and placement to minimize drafts and to permit easy access. Exhaust fans in the wall or ceiling are often used to supplement natural ventilation. In interior bathroom spaces, a mechanical exhaust is, of course, essential.

It is essential that all surface materials used in the bathroom have moisture-resistant finishes.

Storage

Adequate storage should be provided for current and reserve supplies. Articles in current use should be located near their place of first use. A closet opening from the bathroom and hallway or laundry is convenient for such items as bathroom linen and cleaning supplies. Medicine cabinets should be as large as possible since increasing numbers of toiletries and medicines are being used by American families. Hamper space is desirable for soiled linen and clothes. Install a cabinet with a self-contained hamper, or, in two-story houses, install a chute from the second floor to the laundry. The minimum requirements for storage of bathroom linens, based on recent research, are shown in Table 3.

Increased countertop space

Larger lavatories and increased countertop surfaces provide excellent facilities for light laundry, hair washing, and bathing and dressing the baby.

Children's convenience

Children's height should be considered in the placement of accessory equipment. A dental lavatory can double as a child's lavatory. If a combination lavatory-dressing table is installed, a step-up retractable stool should be provided for children's use.

Mirrors

An atmosphere of luxury and spaciousness is created by mirrors. A full-length mirror is always desirable. Also recommended is a medicine cabinet with a three-way combination of mirrored doors on either side and a mirror in the center.

Safety features

Grab bars should be used vertically for bathtub and shower and should be located for convenient use. They should be of adequate size and securely fastened to sturdy backing or studs. Use nonskid finishes for flooring. Install a door lock that opens automatically from the inside, and from the outside in case of emergency. Locate light switches out of reach of the bathtub or shower—preferably just outside the bathroom. Electric or radiant heaters should be recessed or protected. Provide a lock for medicine compartments.

Drying facilities and accessories

Add extra racks for drying women's hose and other light laundry. Racks may be concealed in well-ventilated cabinets, which, if desired, may include a receptacle for a low-wattage light bulb to facilitate drying. Sufficient robe hooks, bag hooks,

*Space required for one person to assist another at the toilet (dimensions not shown in Fig. 1).

and toothbrush holders should also be provided.

Accessibility

A bathroom should generally be accessible to each bedroom without requiring passage through another room. A bathroom is desirable near principal indoor living, work, and play areas, and for guest use.

BASIC DIMENSIONS

Space is required not only for the use of particular fixtures but also between fixtures for cleaning purposes and for assisting another person (such as a small child or elderly adult). These last two factors are often completely overlooked. For economy of space, required clearances for each fixture may sometimes overlap (Fig. 8).

BATHROOMS

Recent research has provided some recommendations for the space required around the three basic fixtures: lavatory, toilet, and bathtub and shower. The basic clearances are given in Tables 1 and 2 and Figs. 1-3.

Miscellaneous activities

In planning the bathroom, the designer should remember that families with infants usually prefer to bathe them in the bathroom. The lack of adequate space has, in the past, caused many families to use the kitchen, which obviously is less appropriate for this activity than the bath. The minimum space needed to bathe and dress an infant is 1 ft 6½ in. deep by 4 ft 11 in. wide by 3 ft high.

In addition, other important activities are often performed in the bathroom. Most women, at least occasionally, launder small items in the bathroom, and provision for this should be made. Many adults, and children, like to use the bathroom for dressing. Since this requires a considerable amount of space, it should be provided only when requested.

ARRANGEMENT

Bathrooms can be classified into four categories: (1) The conventional three-fixture bath; (2) The larger, compartmented bath; (3) The lavatory or "guest" bath; and (4) The "utility" bath.

Three-fixture bath: The conventional three-fixture bath without separate compartments has traditionally been designed for the occupancy and use of one individual at a time. This type of bath, with combination tub-shower, averages about 40 sq ft of floor space (Fig. 5).

Compartmented bath: To avoid the excessive humidity common in the usual three-fixture bath, tub and shower may be located in a separate compartment, with or without an additional lavatory. This plan also affords greater privacy for use of the toilet. Separate doors, possibly with a small entry, are desirable. Connecting doors between compartments are also possible but are not recommended as the only means of access (Figs. 6 and 7).

Another variation is to make the toilet a separate compartment, affording complete privacy. In even the minimum-sized bath of this type there is generally room for an additional lavatory, and the bath proper is often enlarged into a combination bath-dressing room. Dressing tables may be a combination of lavatory and table or individual fixtures. In the latter case, tables should be sufficiently far from lavatories to prevent damage from splashing water.

Table 3. Minimum dimensions for storage of bathroom linens, including allowance for handling

Adapted from Storage Requirements for Household Textiles, A. Woolrich, M. M. White, and M. A. Richards, Agricultural Research Bulletin 622, U.S. Department of Agriculture, Washington, D.C. (1955).

Item	Number	Minimum dimensions, in.

Bases for towel bars, shelf brackets, door stops, and hooks				•	•		•
Grab bars and soap or sponge holders	•	•					

*Some toilet-paper holders are 6x10 in. Radiant heaters are 15x15 in. or larger.

A still greater expansion of this plan provides a separate dressing room and connecting bath, with a compartment for the toilet. The required floor space ranges from 110 to 140 sq ft.

In all plans for baths, showers should be included, either as stalls or over tubs.

Guest bath: The lavatory, or two-fixture "guest" bath, for living portions of residences may vary in size and appointments from a minimum area of about 14 sq ft to rooms of 22 to 25 sq ft or larger when a dressing table is included (Fig. 4).

Utility bath: The "utility" bath provides an area larger than the minimum size required for the three basic fixtures, for other functions, such as laundering.

DOORS AND WINDOWS

Bathroom doors can be as small as 2 ft wide, except for utility bathrooms, for which doors should be not less than 2 ft

4 in. wide to permit passage of equipment as required. In general, bathrooms should contain only one door.

Door swings should be arranged so that: (1) The door cannot strike any person using any fixture; (2) The door will shield or conceal the toilet; and (3) The door may be left fully open for ventilation in warm weather.

Customarily, doors swing into the bathroom. If hall areas are sufficiently large, doors to small bathrooms can sometimes be designed to swing out. In-swinging doors should be set to clear towel-bars or radiators. Sliding doors are frequently desirable, as space savers, between various compartments within the bathroom.

The shape and position of bathroom windows is important from the standpoint of light, ventilation, and privacy. Generally, the higher the window, the better. Preferred locations include: clear wall space reserved for portable equipment, space

At lavatory

- A. Mirror and medicine cabinet. Size is governed by use of shelf or shelf-topped lavatory; mirror should swing 7 in. over any shelf. (A.1) Fixed mirror is desirable immediately above lavatory for children 7 to 14 years.
- B. Shelf. Preferably recessed flush with wall. May be part of medicine cabinet or part of lavatory.
- C, D, and E. Soap, toothbrush, and tumbler holders. May be separate units or combined; flush or projecting type.
- F. Receptacle for electric razor and hair dryer. Should be above and to right of lavatory; dead front type.
- G. Razor blade disposal slot.
- H. Towel bars. May be at level of shelf or lavatory top. In congested space provide upper bar for face cloths, lower bar for towels.

Telescoping utility rod
—4 to 14 in.

Robe hook

Electric towel rack—
26x13x3 in. (nominal)

Grab bars

Straight bars—9, 12,
15, 18, 24, and 30 in.

Angle bars—16x32 in.

At bathtub

- A, B, and C. Shower head, shower controls, bath valves and spout. Location is optional with client but must be accessible from outside of tub. See shower stall for recommended heights.
- D. Combination soap and sponge holder and grab bar. Draining-lip type preferred.
- E. Vertical grab bars. Optional but recommended.
- F. Towel bar. Do not use over tub equipped with shower.
- G. Curtain rod. Keep within inside face of tub. (G.1) Alternate; glass shower enclosure in place of curtain. Various types, with and without doors, are available.

Not illustrated

- Full-length mirror. Usually on door.
- Bathroom scale. May be built-in or portable.
- Linen hamper. Optional; may be part of cabinet-type lavatory, built-in or portable.
- Auxiliary heater. Built-in radiant type desirable; should radiate toward open floor space.

Residential

BATHROOMS

Fig. 7 Compartmented plans.

over a dressing table, and space above or on either side of the lavatory. Windows should not be placed over the bathtub unless they are of the casement or awning type opened by a crank. A window behind the toilet is seldom desirable. Skylights may be used to serve top-floor bathrooms if they are large enough to provide adequate light and ventilation. Inside bathrooms without exterior windows are sometimes used but require a dependable system of exhaust ventilation by natural or mechanical means, and greater artificial lighting in lieu of natural light.

ACCESSORIES

The medicine cabinet should be related in size to the type of bathroom or toilet. For guest baths or toilets, space is needed only for dentifrices, shaving accessories, toilet preparations, and a few simple remedies. A bath serving several bedrooms may require a complete supply of medicines in addition to the items mentioned above. Every bathroom should have a storage closet for cleaning utensils and supplies and for reserve stocks of toilet paper, towels, and sundries.

Floor space should be left in every bathroom for portable accessories desired by the owner or needed on occasion for the care of infants or invalids. Also consider allowing space for such items as scales, stool or seat, infant's bath and dressing table (portable type requires about 3 by 4 ft of floor space in use), soiled-linen hamper, exercise devices, dressing table or vanity with bench, and ultra-violet radiation equipment.

Towel bars should be ample in number

and length to serve the needs of each member of the family regularly using the bathroom, or of guests likely to use its facilities, before supplies can be replenished. For each person regularly using the bathroom, there should be separate bar space for bath towel, face towel, and face cloth, as well as an additional rack for guest towels.

Linen storage may consist of towel cabinets recessed in the thickness of plumbing walls (either over fixtures or as full height cabinets) or may be expanded into complete linen closets. Dressing-room baths may include completely fitted wardrobes. (See Table 3.)

Minimum-sized bathrooms and toilets require special planning to ensure ade-

quate wall space for essential accessories (Table 4).

Drawings by LARCH RENSHAW, AIA

STORAGE

"A place for everything and everything in its place" is the slogan for closet designers as well as housewives. Modern closets should be planned for the storage of the particular clothing or objects of the individual or the group using the space. An accurate list of the objects to be stored is necessary for the scientific allotment and arrangement of space and facilities. A "margin of safety" of some 25 per cent increased capacity should be allowed for the usual accumulation of additional belongings. It is better to have too much space than not enough. Much can be stored in little space if sufficient thought is given to the arrangement of the space and the equipment. Too many closets have unused and unusable space due to poor planning.

Good closet design requires planning, arrangement, and fixtures contributing to:

1. Convenience
 - a. Ease of access
 - b. Maximum visibility
 - c. Orderliness
 - d. Maximum accessibility
 - e. Maximum of used space
2. Preservation
 - a. Of pressed condition
 - b. Of freshness (ventilation)
 - c. From moths
 - d. From dust
 - e. From pilfering

The above are not all simultaneously obtainable, and some are mutually exclusive; for instance, eliminating doors gives maximum availability but minimum security from dust, moths, and pilfering; adhering to the principle of maximum accessibility would result in unused space at top and bottom of closet.

Modern closets, by the efficient arrangement of space and fixtures, accommodate much more clothing and material than the inconvenient, space-wasting closets of a few decades ago. The modern closet often replaces pieces of furniture and thus provides a greater amount of free, uncluttered space in the room.

Doors should open the full width of the closet whenever possible. In most cases the most efficient and economical doors are the usual hinged type. Two doors for a 5-ft closet will eliminate dark, inaccessible, hard-to-clean corners. Hooks, racks, and accessories on the backs of swinging doors increase efficiency by using otherwise unoccupied space in the closet.

Alternate closet closing methods may involve more complicated or more expensive construction, though they may obviate the objection that swinging doors form an obstruction in the room. Sliding doors can expose the entire interior of the closet to view and make it immediately accessible. Such doors do not block traffic. Sliding doors, however, do not permit the use of special door fixtures such as tie racks, shoe racks or bags, hat hangers, or mirrors, which are handy and easily reached when attached to a hinged closet door. Banks of wardrobe-type closets with sliding doors are becoming more and more popular. Fitted with drawers or trays, they take the place of bureaus, chests, and chiffoniers and make for more spacious, uncluttered rooms.

Doors which expose the full width of the closet are preferable for both visibility and accessibility. "Walk-in" or "walk-through" closets naturally use more area than others with no "circulation." In some rooms, however, a single door to a large "walk-in" closet may be justified by the need for maximum wall space for furniture.

Some of the various closing methods are shown in Fig. 1.

Fig. 1. Closet closing methods

Lighting is considered essential and standard in the modern closet unless room lights are located to illuminate fully all portions of the closet. A single tubular or bulb light with a diffusing reflector placed just above the door inside the front of the closet is usually sufficient. Automatic door switches are convenient.

Ventilation is often desirable, particularly in hall closets where damp outer garments or work clothes might be stored. It can be accomplished readily by providing louvers in the closet door or by using louver doors.

Types of closets

Closets are required for various purposes, in different parts of the house. Some have already been mentioned in other sections of this volume: kitchen supplies; dinnerware, glassware, and table linens (discussed under "Kitchens"); and bathroom supplies (discussed under "Bathrooms"). Closets must also be provided for the storage of clothing, bedding, cleaning equipment, books, magazines, and phonograph records, toys and other children's and adults' recreation equipment, and certain items such as luggage that are used only seasonally or infrequently. The discussion here relates only to "active" storage space.

Clothes closet: For clothes closets in bedrooms or dressing rooms, 2 ft is standard depth (2 ft 6 in. if a hook strip is to be used). (See Fig. 2.) This permits clothing to be on hangers on poles, with sufficient clearance. Clothing lengths are shown in Fig. 3. Clothes closet width, parallel to the doors, should be from 3 to 6 ft per person, depending on amounts of clothing and

Fig. 2. Closet depth and hanger sizes

whether drawers or trays are to be provided in the closet or wardrobe for such items as have in the past been kept in bureaus or other pieces of furniture. Some typical closet plans are illustrated in Fig. 4; suggested layouts for bedroom closets for men, women, and children are shown in Figs. 5-9.

Coat closets, located near the entrance doors, are sometimes made 2 or 3 in. deeper than bedroom closets, to allow for the bulkiness of some overcoats, and to permit better air circulation around the garments which are often damp when hung in the closet. Several designs for coat closets are shown in Figs. 10 and 14.

Closet for cleaning equipment: The dimensions of the storage space needed for cleaning equipment will depend in large part upon the type of vacuum cleaner used: horizontal, upright, or canister; recommended dimensions for each type are shown in Fig. 11. Since families may change from one type of vacuum cleaner to another, the cleaning closet should be made large enough for any type. The closet should be located as near the center of the house as possible, and should be provided with a convenience receptacle so that the vacuum cleaner can be left connected and can reach most areas of the house. A suggested design for a cleaning equipment closet is shown in Fig. 12.

Storage for bedroom linens and bedding: Limited and liberal lists of articles of bedding that require storage, and the minimum dimensions of the space required, are shown in Table 1.

Fig. 3. Sizes of clothes hung in closet

FHA¹ requirements for linen closets are as follows: minimum interior dimensions, 18 in. wide by 14 in. deep (24 in. maximum); shelves spaced approximately 12 in. on center vertically; highest shelf, 74 in. above

the floor; minimum total shelf area for one- and two-bedroom house, 9 sq ft, for three- and four-bedroom house, 12 sq ft; drawers may replace 50 per cent of the shelves. These are minimum dimensions, and about twice this amount is recommended, especially if both bedroom and bathroom linen are to be stored. A suggested layout for such a combined linen closet is shown in Fig. 12.

¹Minimum Property Standards for One and Two Living Units, *Federal Housing Administration, Washington, D.C., revised July, 1959.*

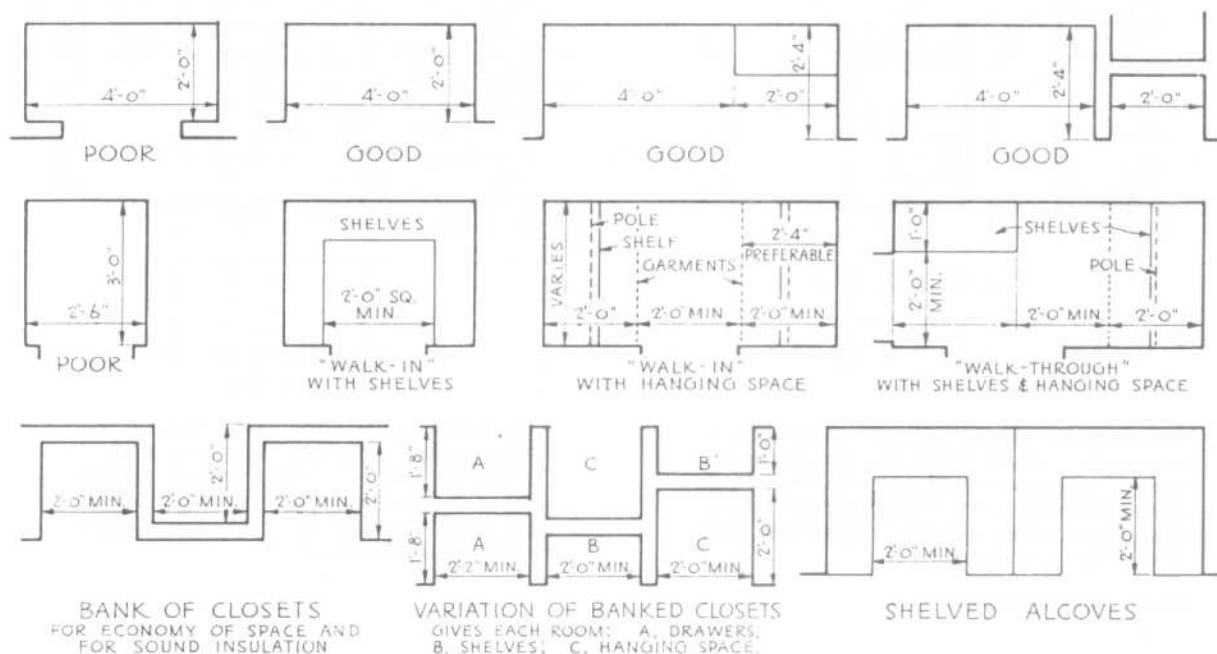

Fig. 4. Typical closet plans

A minimum size closet of a usual type. Shoes can be stored on the raised shelf-rack and three additional pair on the floor in front of the rack. Door could be arranged for hats as shown below, leaving shelf for other storage.

Minimal closet arranged to make shoes more visible and reachable. There is space for hats without crushing or for night clothes hooks if hats are normally stored in a hall closet. Neckties might be in two tiers.

An alternate to the scheme above giving maximum view of shoes and an additional shelf. Trousers would have to be folded over the crossbar of the suit hanger rather than being hung separately from the pole with trouser-hangers.

A four-foot closet with seven drawers for shirts, socks, underwear, etc., and a vertical tier of shoe racks (as above). Night clothes and bathrobe hooks are best on the right hand door, necktie racks flat against the left hand door.

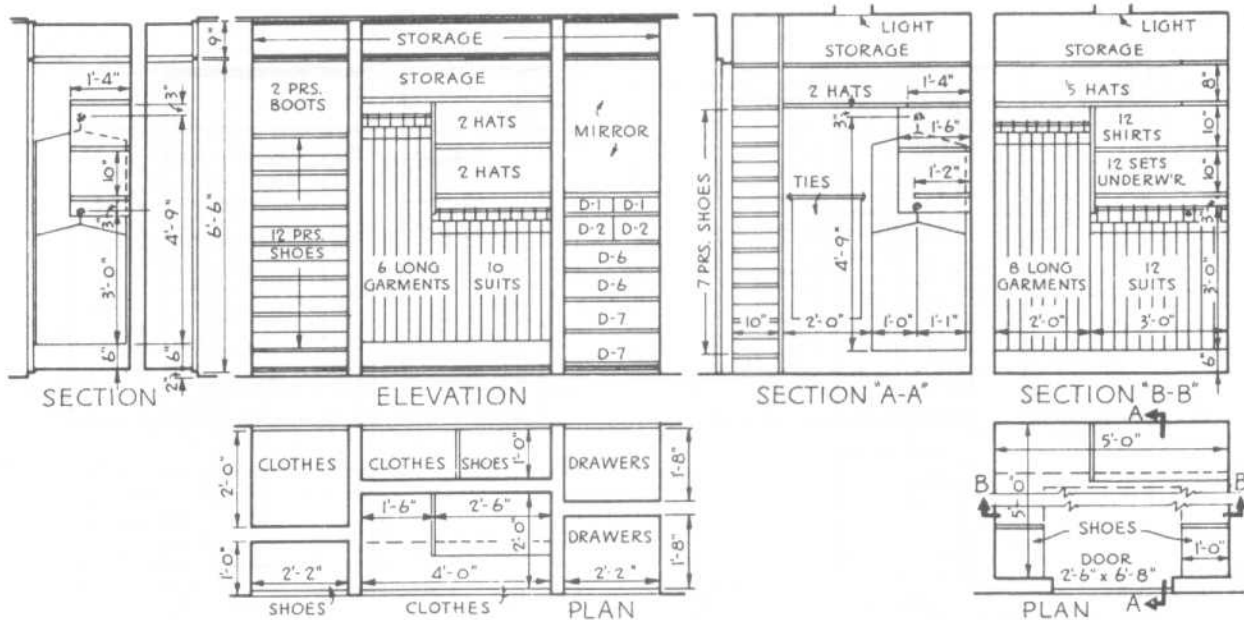

Fig. 5. Bedroom closets for men

Another four-foot closet with ten standard drawers conveniently arranged. Shoes are placed tandem above the drawers for visibility and reachability. Poles are one above the other, requiring reaching.

A solution to the shallow closet problem. A pull-out rod takes care of the suit, coat and trouser hanging. Five drawers take the place of a small bureau or chest. Shoes are at "no stoop, no squat, no squint" levels.

Wide wardrobe closets of more luxurious size planned as part of walls separating two rooms. Four doors, sliding or swinging, can be used. Lower portion of shoe-tiers could be replaced with mothproof "dead-storage" drawers.

A deep walk-in closet. High tiers of shoe racks flank the door jambs. Shelves for live and dead storage on three sides, upper levels. Suit poles range the back wall. Ties are on the left wall, night clothes hooks on right wall.

Fig. 6. Bedroom closets for men

A small closet with shoe racks at the side under short hanging garments. Additional shoe pockets might be placed on the door under the hanging shelves. These handy shelves fold into the space in front of the hat and storage shelves.

An alternate minimum closet arrangement with a high pole for long dresses. Two drawers below the shorter hanging garments. Depth of closet permits a door type shoe rack and a hat rack. Wide hats can go on upper shelf.

Alternate to closet above. It provides a high pole for hanging evening dresses and a lower pole for other dresses and suits. A large hat shelf is provided above the low pole as well as a hat rack and shoe pockets on the door.

A four-foot closet combining hanging and shelf space with drawers for stockings, underthings, and what-not. Shoes are easily seen and chosen from the almost eye-level cleat rack above the drawers. Hat storage on the shelves.

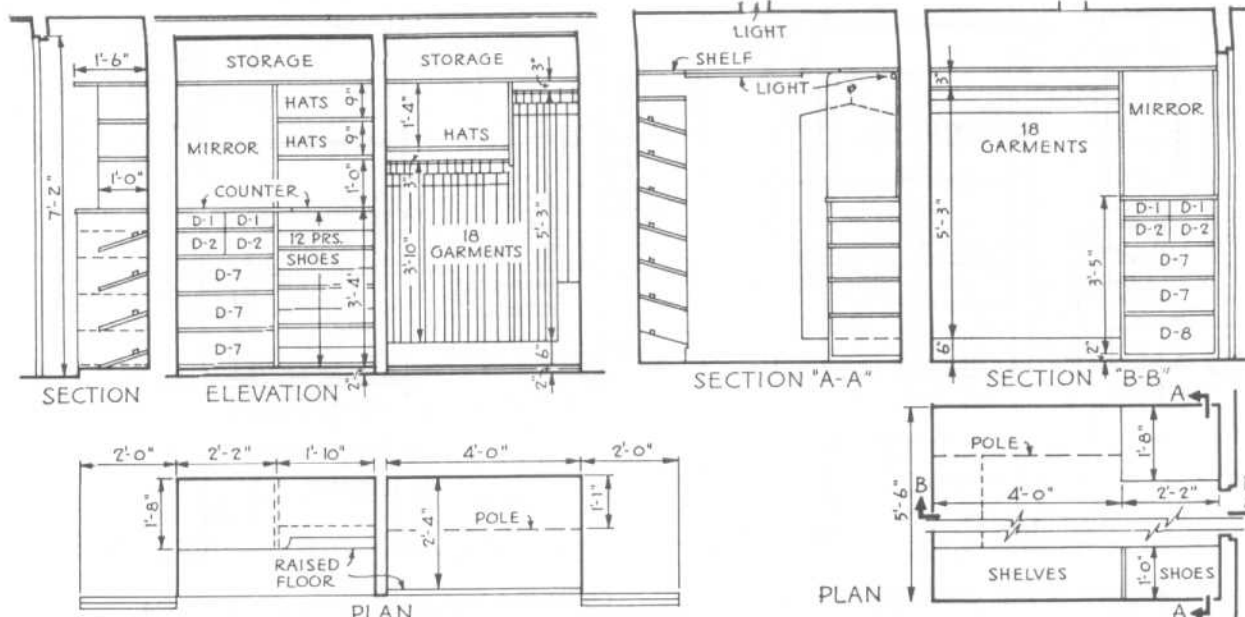

Fig. 7. Bedroom closets for women

Another four-foot closet with a short cantilever pole at the left allowing two-decker hanging. Closet drawer space would naturally be supplemented by a bureau or other furniture. A shoe rack on the door would increase capacity.

The shallow closet problem solved by the use of a pull-out rod firmly anchored to the back wall. Drawers again at lower right with cleated shoe shelves above, and hat shelves above them. Drawers may have to be shorter than standard.

Large double wardrobe type closet, almost half devoted to hanging space. Left half fitted with large and small drawers and wide shelf-counter with mirror above. Sliding doors may be preferred and center partition minimized.

A walk-in closet, shoe racks and shallow shelves at one side drawers and hanging pole at the other. Drawers next to door are convenient but hazardous if left open. They could be placed at the back with hanging space near door.

Fig. 8. Bedroom closets for women

CLOSETS

Closet for infants up to about 5 years old. Low hanging pole shelves and drawers permit habits of care and orderliness to be developed at an early age. Upper part would be used by adults. Note two sets of doors.

Small closet designed for a child of from 6 to 10 years. Pole at higher but easily reached level. Drawers and shoe racks at convenient heights. Ample shelf room provided above for the storage of possessions.

Alternate, and larger, closet for an infant up to 5 years of age. Trays or drawers for folded garments at an upper level for adult use. Hanging space, drawers and shelf available to child using the lower doors.

Closet for youngster up to 10 years old, providing greater length of hanging pole and different shoe arrangement, trays instead of cleat racks. A large shelf for hats, toys, or "collections" available to child.

Fig. 9. Bedroom closets for children

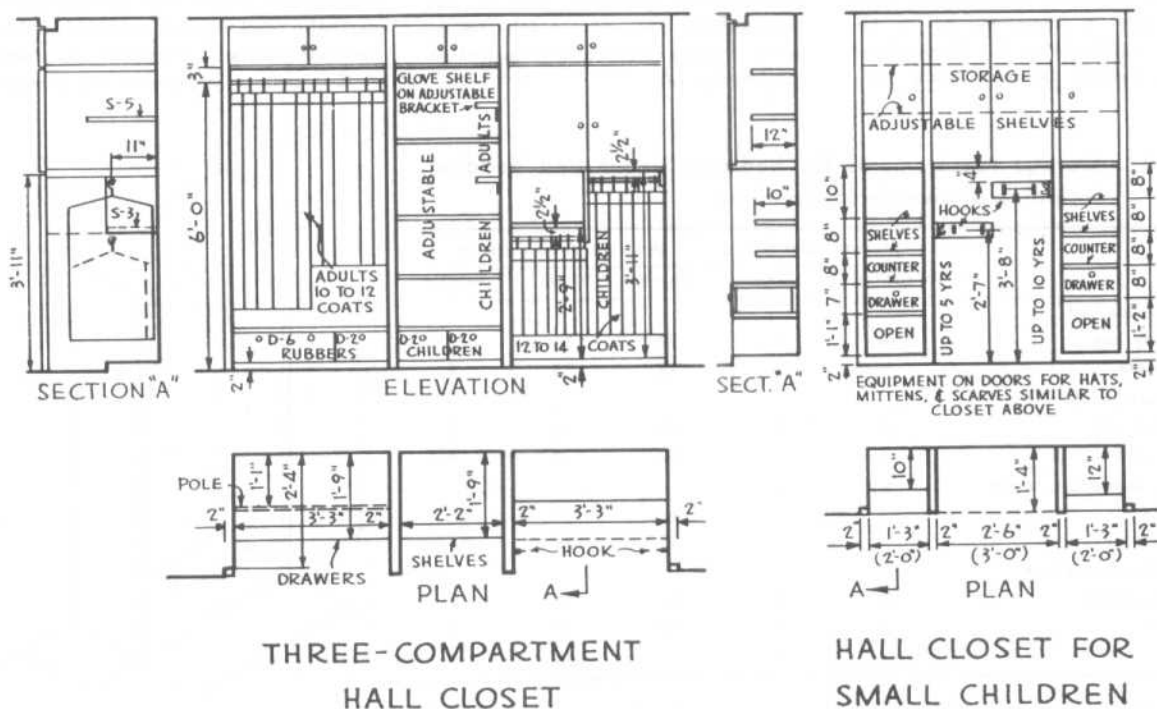

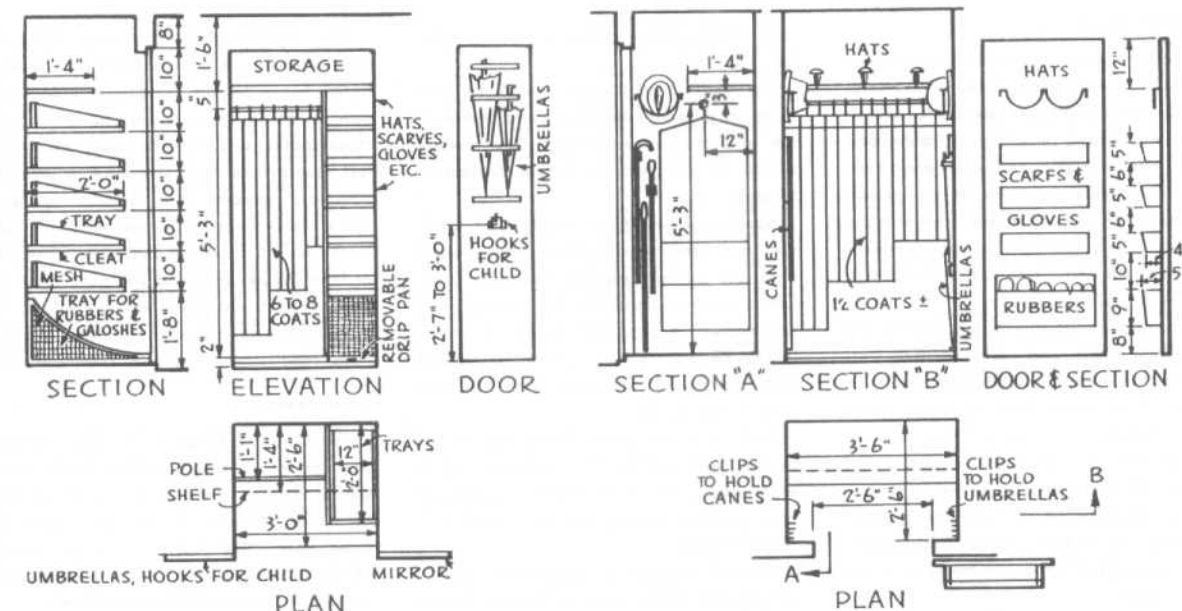

Fig. 10. Coat closets

CLOSETS

Miscellaneous storage

A large variety of other articles that are in regular use must be stored somewhere. Included in this category are books, magazines, phonograph records, card tables and chairs, games, movie and slide projectors, screens and film, toys, sports equipment, and tools. If adequate and conveniently located built-in storage is not provided, then portable units (furniture) will have to be used for this purpose.

Book storage is usually required in the living room, study, and each bedroom. Most books (85 per cent) can fit comfortably on shelves 8 in. deep (front to back); some books (10 per cent) need 10-in. shelves, and a few (5 per cent) require 12-in. shelves. Vertical spacing between shelves varies from 8 to 16 in., with the greatest use in the 10 to 12-in. range. Horizontally, books average 7 to 8 volumes per linear foot of shelf.

Phonograph records (12 in.) in albums require shelves with a clear height of 14 in. and a depth of 15 in. (14 in. for long-playing records in cardboard folders).

Card tables are usually 30 in. square but may be as large as 36 in., and are 2 to 3 in. thick when folded. Folded chairs vary widely in dimension, but a fair average is 30 by 16 by 3 in. Space should also be provided for cards, score cards,

rule books, poker chips, chess, etc. (see Fig. 13).

Toy and game storage should be provided in children's bedrooms and wherever the toys are regularly used. Toy storage should be designed for future conversion to other use.

Sports equipment, especially golf bags, skis, and camping equipment, may present a serious storage problem. For some families, a separate closet for this purpose may be justified; a suggested design is shown in Fig. 13. Such a closet should be located near the outside entrance which is most used by the family.

Tools and associated items should, of course, be stored in the workshop, which every house must have. Paints, because of odor and fire hazard, are best stored outside the house.

General storage is required for bulky, seldom-used items, such as trunks, boxes, and extra furniture.

Outdoor storage (i.e., directly accessible from outdoors) is required for lawnmowers, wheelbarrows, sprays, rakes, and other garden tools and equipment; for snow shovels and sleds, ladders, screens, and storm windows; for outdoor furniture, barbecues, hammocks, croquet sets; for bicycles, tricycles, scooters, and perambulators (see Fig. 14).

These last two types of storage (general and outdoor) were provided in the traditional house by the basement, attic, and garage. Modern houses may have none of these spaces, and, in such cases, the architect should take particular care to provide adequate general and outdoor storage space. FHA minimum requirements are 200 cu ft plus 75 cu ft per bedroom, of which at least 25 per cent and not more than 50 per cent should be indoors. Again, it should be emphasized that this is a minimum requirement; more is recommended.

Basic elements

The standard elements of closet storage are shelves, drawers, poles, hooks, and special fixtures. Practically any object can be stored efficiently by one or another of these means. The choice and arrangement of the fixtures depend on the amount and nature of the materials to be stored.

Shelves: Shelves are simple and inexpensive to install, require a minimum of effort to use, and are adaptable to the storage of many types of things, especially those of odd or bulky shape, folded articles, and, of course, books, magazines, etc. However, if open, they are exposed to dust. Also small objects become hidden behind one another if the shelves are deep. A 12-in. shelf is usually adequate for most

Table 1. Storage requirements for bedroom linens and bedding, including allowance for handling

Article	Median number		Minimum dimensions, in.		
	Limited	Liberal	Depth	Width	Height*
Sheets, double bed					
Everyday use	6	6	12	14	12
Guest use	—	4	12	14	9
Pillow cases (pairs)					
Everyday use	5	5	12	8	8
Guest use	3	3	12	8	6
Blankets, comforters, quilts	4†	4†			
Pile of 4			23	19	26
2 piles of 2			23	38	14
Bedspreads, double bed					
Cotton damask	2	2	16	15	9
Chenille	1	1	18	16	8
Pillows		3	18	26	17

* For storage on fixed shelves. For storage on sliding shelves or in drawers, deduct 1 to 2 in.

† Number of warm bed coverings owned is normally larger than this, but balance can be stored in less accessible location than linen closet.

Upright type W = 28 in.
Canister type W = 35 in.
Horizontal type W = 41 in.

things. Articles of larger dimensions or greater depth should have their special places; linens, for instance, are frequently folded for a 16-in. shelf.

Drawers: Drawers are growing in popularity in closet design because they accommodate numerous articles with a minimum of space and a maximum of convenience. They provide practically dust-free storage and present a neat appearance even when carelessly used. Drawers of different widths and depths make possible classified "filing" of different items, thus providing a great saving in time and an incentive to orderliness. A cabinet made up of a battery of standard drawers, selected for the storage of the known possessions of the user, can easily be made from a comprehensive list, with allowance made for the accumulation of additional items.

Drawer construction is cabinetwork requiring both skillful craftsmanship and the best materials. They must operate freely under all seasonal and climatic conditions.

A recent logical outcome of this situation has been the development of molded plastic drawers in a variety of stock sizes. Fronts of various materials can be attached. All that is required of the builder is the construction of the supporting enclosure.

Poles: Hanging pole length can be estimated roughly at 3 in. per hanger for men's suits (4 in. for heavy coats) and 2 in. per hanger for women's clothing. Height of pole above floor should average 64 in., but should be adjusted to the individual. Clearance between pole and shelf above should be 3 in. Hardwood poles 1 in. in diameter should have intermediate supports if over 4 ft in length. Consult manufacturers for special-purpose hanging rods, extension poles, brackets, etc.

Hooks: A variety of hooks is available.

Special features: Such special features as shoe and hat racks and miscellaneous racks are on the market and greatly increase convenience in storage.

Residential APARTMENTS

By J. L. GRUZEN and J. J. KOSTER, Gruzen and Partners

INTRODUCTION

At the time of this writing, it is anticipated that within the next 15 years in the United States it will be necessary to construct as many new housing units as have been constructed to date.

This need for new housing, considered against a background of continuing urbanization, clearly indicates that an increasing proportion of an expanding housing market will be devoted to multifamily types of housing or apartments. The inevitability of this trend contains a challenge to the architect to do more than merely meet a statistical demand. He must rather address, identify, and solve the problems of multifamily building types as an attractive alternative to freestanding single-family buildings.

This article will deal with multifamily living in general, with some additional attention to the problems of the medium- and high-rise building type (i.e. building types which require a degree of vertical servicing).

GENERAL

The process of designing an apartment building may be graphically depicted in a general way as in Table 1. This article will be developed in the same sequence as Table 1. It must be borne in mind that, as with any design development, the evolution of an apartment building design is not a sequential process but a process of continuing interaction, feedback, and reevaluation, and that the number and complexity of events will vary according to the program, scope, and funding sources involved. The sequences shown are labeled as *program development*, *site analysis*, *building planning*, and *building design*.

Program development is for the most part evaluation of information over which the architect has relatively little control but which shapes the project in a basic way.

Site analysis involves evaluation of physical data which must be recognized, identified, and weighed by the architect in making basic design decisions dealing with site use, allocation, and development.

PROGRAM

Market Analysis

A market analysis and program formulation may precede the retention of an architect; however, to an increasing degree clients solicit the aid of an architect in these areas. An investigation of the potential market should consider existing market conditions and trends with regard to

1. Type of occupancy
 - a. Rental
 - b. Cooperative
 - c. Condominium
2. Price (rent, maintenance, etc.)
3. Amenities
4. Apartment size (area and number of rooms)

TABLE 1

TABLE 2 Comparative Program Elements—Market Range

	Low	Medium	High
Living unit			
Living	Minimum areas: combined living, dining and entry areas	Larger room sizes: dining alcove, entry alcove	Generous room sizes: separate dining room, separate entry foyer
Kitchen	Minimum counter top and storage; Standard appliances	Additional counter top and storage; snack bar, better appliances, space for dishwasher	Ample workspace, counter top, and storage; built-in appliances, wall oven, dishwasher, eat-in kitchen
Bedrooms . . .	Minimum closets	Walk-in closets	Dressing rooms, storage closets, built-in accessories
Baths	Minimal bath with standard fixtures and accessories; minimum finishes	Higher-quality fixtures, finishes, and accessories; extra half bath at entry or master bedroom	Additional baths and half baths with custom cabinets and fixtures; stall showers, etc. powder room; luxury finishes
Support facilities			
In apartment	Few extras limited to security	Intercom, door signal, balconies, unit air conditioners	Doorman and telephone, large balconies, central air conditioning, service entrance, servants' quarters
In building	Laundry facilities, minimum lobby	Laundry room, commercial space, community room, central storage	Attended parking, convenience shopping, service elevators, doorman, closed-circuit TV security system, valet service, meeting rooms, health club, sheltered swimming facilities
Site	Open parking, drying yard	Secure open or sheltered parking, outdoor play and sitting area, swimming pool	Gardens, recreation areas, country club amenities, swimming pool

6. Vacancy rates

6. Vacancy rates

7. Public facilities (transportation, schools, shopping, recreation)

Program items to be resolved include

Price range. What segment of the market is the project to be aimed at?

Amenities. Identified in Table 2 as support facilities and closely interrelated with price range.

Scope. How many units?

Distribution. Percentage of each type of unit.

Building type or types.

Funding

In many cases a market analysis will conclude that conventional private financing is not economically feasible and that some type of public or semipublic assistance is required if a project is to proceed.

There are a number of sources of such assistance at both federal and state levels. The FHA (Federal Housing Administration) and PHA (Public Housing Administration) are well-known examples of such agencies. As a rule, an agency which provides assistance also requires conformance to agency standards, and frequently such an agency will require approval of or participation in program development.

While the client, local authorities, and funding sources will usually institute basic program direction, it nevertheless remains the responsibility of the architect to catalyze these decisions and formulate the finished program.

Density

Figure 1 compares relative densities of various urban and suburban situations. It is helpful to "have a feel" for the physical reality of density figures as an aid in visualizing possible solutions and to anticipate implications of decisions which are made during program formulation.

ZONING AND CODES

General

Zoning and building codes are of basic importance to any project; and of all types of projects, those which involve housing tend to be regulated to a greater degree by zoning ordinances and codes.

Appropriate local and regional authorities should be contacted in order to determine the type and extent of limitations or controls which may be imposed on a project and, further, to gauge the discretionary powers and flexibility of the governing authorities. To an increasing degree, the philosophy of zoning is changing from one of restrictive limits and controls to an approach which attempts to lead and influence community growth. Many communities and regional authorities have guiding master plans which deal with long-range development and evaluation. The conceptual and planning freedom of the architect is linked with these considerations.

Failure to pursue a thorough investigation of these controls can result in serious problems later on in project development.

Controls

Zoning is concerned principally with questions of use, bulk, density, and location.

Use, bulk, and density are usually controlled

Fig. 1 Comparative densities.

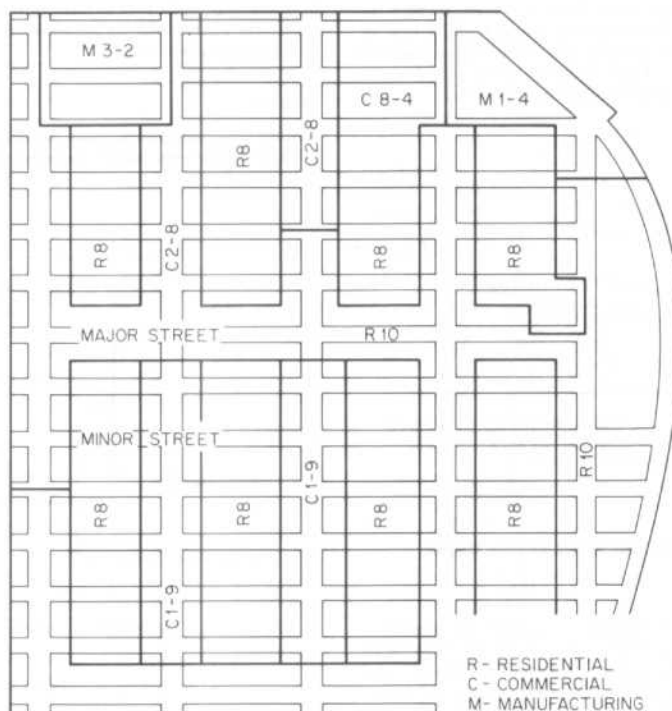

Fig. 2 Zoning map example.

Fig. 3 Setback diagrams.

Residential

APARTMENTS

on the basis of districts which are generally shown on maps and explained in an accompanying text (Fig. 2).

Uses may be designated as, for example, residential, commercial, manufacturing, and, in some cases, park or recreational. Mixed uses are frequently allowed, and for large housing projects it is considered advantageous to incorporate retail shopping, entertainment, and dining facilities into a program.

Location of buildings is controlled in order to prevent oppressive proximity of building masses. Formulas or diagrams which relate to variables such as building height and density are applied to locate buildings with respect to property lines and/or one another. (See Figs. 3 and 4.)

Density regulations limit the number of people per site-area unit. The basis for density determination will vary from regulation to regulation. Density may range from a low of ten or fewer people per acre in low-density districts to a high of up to 1,500 or more per acre in the highest-density districts.

Fig. 4 Building spacing and location diagram.

Bulk is frequently controlled by floor-area ratio, which limits total buildable floor area as a multiple of the site area. In contemporary zoning regulations, floor-area ratio for apartment buildings will range from a low of 1 or less to a high in the range of 14 to 18 in dense metropolitan areas.

Building codes are less regional and vary less than zoning regulations. Many localities adopt national or state building codes as their standard. Such codes are concerned with health and safety requirements such as light and air, access, egress, construction standards, minimum dimensional standards, fire detection and protection, and fire equipment access.¹

Standards

Similar to zoning and codes and equally important in many cases are governmental agency standards, which apply when public or semi-public funding sources are involved or mortgage standards if private funding is involved.

The need for a thorough initial investigation and continuing review for conformance with controls imposed by zoning, codes and agencies cannot be overemphasized.

¹Note: Local fire departments and fire insurance groups may exert more restrictive controls than the above-mentioned codes.

SITE CONSIDERATIONS

Site Characteristics

Physical characteristics of a site may impose limitations on a building program; therefore an early analysis of site data and conditions should be undertaken by the architect in order to ascertain and evaluate such limitations.

Borings and samples taken at the site will provide information regarding location and extent of rock, bearing capacity of the sub-surface strata at various levels, and the level of a water table.

A survey indicating boundaries, contours, or spot elevations is necessary and, in the case of difficult sites, such a survey may indicate terrain and other conditions which will strongly influence design decisions. Limitations imposed by difficult terrain—in addition to those imposed by local laws or ordinances—may limit such items as location of driveways and parking entrances.

Utilities

Availability, adequacy, and location of site utilities enter into basic decision making. A

Site Elements

Figure 5 diagrams possible relationships among site layout elements which normally occur in apartment development. As suggested by the diagram, it is desirable to limit cross traffic among circulation elements such as vehicular access and pedestrian access and to maintain proximity or easy access among activity elements such as the dwelling unit, recreation, and parking.

The relationships may be horizontally or vertically arranged, depending on density or tightness of a site. Emphasis on the importance of certain relationships may vary with the program; however, the basic elements and relationships remain. Figure 6 shows examples of different arrangements of the site elements—arrangements which reflect program density relative to site area.

Building Access

Figure 7 diagrams various means of building access and internal circulation, each with different advantages and degrees of suitability to specific design solutions.

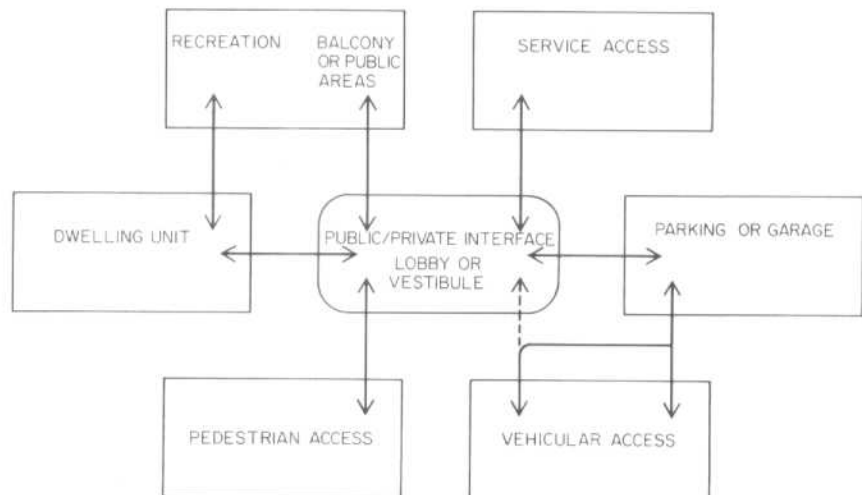

Fig. 5 Site element diagram.

building or buildings may be located so as to minimize expensive service runs. Inadequacy or unavailability of certain services may require on-site generation or disposal facilities.

Large Scale

Large-scale residential developments involve special problems and opportunities. Closing or rerouting of streets wholly within a project is frequently undertaken and can free up area, eliminate restrictions of a street grid pattern, and generally change the scale and feeling of a project. When through streets within a project are closed or otherwise restricted, compensatory widening and improvement of peripheral roads is usually in order not only to offset the effect of the closings but also to accommodate the increased traffic flow generated by the project itself. Similarly, shutting down a utility line and adding to demand generally requires compensatory improvement.

Building Orientation

Building orientation may be influenced by a number of factors such as site, view (desirable or undesirable), sun, and prevailing winds. Closely interrelated to building orientation is the question of internal circulation and floor layout of the building. Figure 8 indicates how different layouts lend themselves to solutions of site problems.

BUILDING CONFIGURATION

Floor Shape and Size

The shape and size of an apartment building can have significant influence on the cost and consequently the feasibility of a project.

The shape of the repetitive typical floors influences the cost of constructing and enclosing the floors. For purposes of economy and efficiency, building shape should be such that expensive exterior walls are minimized in

Fig. 6 Site element relationships.

Fig. 7 Building types.

ratio to area enclosed and that breaks and direction changes in the perimeter are minimized. (See Fig. 9.)

Area of a typical floor may affect costs. For example, pouring of a typical tier in a cast-in-place concrete building is a continuous process and requires a full concrete crew throughout. The area of a typical floor or part thereof should be such as to efficiently utilize the day's productivity of a concrete crew. Similar analysis and considerations should be applied to other building techniques or systems.

Building Height

The cost of a building may be affected by building height. A building may be of such height that it exceeds prevailing capacities in terms of available construction equipment and contractor experience. In addition to considerations of what is possible, there are considerations of what is practical and efficient from a cost standpoint. Of the various mechanical systems which serve an apartment building, each has various increments and "step-up" points. For example, there is a situation such that the addition of a single extra floor could require a substantial increase in elevator service either through an additional elevator or an expensive increase in elevator speed. Similar situations exist for heating, cooling, plumbing, and ventilating systems, and opinions of the various consultants in these areas should be solicited.

Length and Width

Additional costs resulting from an increase of building length or width are generally proportionate to increase in area. However, as with other such items, there are step-up points at which there are disproportionately large increases in cost for slight dimensional increases.

Wind Bracing

Wind bracing becomes a structural design consideration in buildings beyond the 10- to 12-story range, and one must then consider measures which may be introduced to resist the overturning tendency due to wind loads. Wind bracing may be achieved by introduction of various structural measures. The extent and, therefore, the expense of these measures may be reduced if the building shape itself contributes to wind bracing. As the diagrams (Fig. 10) indicate, certain building shapes obviously have a greater inherent resistance to overturning.

Fig. 10 Building shapes.

STRUCTURAL SYSTEMS

Concrete

The most common structural system presently employed for medium- to high-rise apartment construction is flat-plate cast-in-place reinforced concrete with randomly placed columns. This structural approach has certain advantages which make it particularly adaptable to apartment construction. (See Fig. 11.)

1. The horizontal services normally required in apartment construction may be imbedded

(a) Typical concrete construction

(b) Typical steel construction

Fig. 11 Steel and concrete structural systems.

within the concrete slab, thereby eliminating the need for a hung ceiling and allowing the flat underside of the slab to serve as the finished ceiling of the space below. This reduces floor-to-floor and overall building height and eliminates the separate construction of a hung ceiling.

2. The possibility of placing columns randomly adapts well to the inherently irregular module generated by a typical apartment floor layout. Columns may thus be "buried" in convenient locations within an efficient layout.

3. As a rule, openings for vertical services may be located at will in this type of structure; however, large openings near columns should be handled with care so as to assure continuity of vertical and horizontal reinforcing.

Steel

Although much less common than cast-in-place concrete, steel frame structures are also employed in the construction of apartment buildings.

The advantages of strength and relative simplicity of erection may recommend steel for use in extremely tall structures or for use in locales where there is limited experience in the use of concrete.

Steel structural frames tend to be laid out in a regular grid pattern, and this in turn regu-

larizes the apartment layout. One should bear in mind that in this type of structure mechanical and structural lines may not coincide.

Limitations

As a rule of thumb, spacing between concrete columns may economically be in the range of 12- to 18-ft centers and spacing for steel columns may range from 16 to 24 ft.

Figure 12 may serve as a guide for sizing of concrete columns in preliminary layouts. Three common bay sizes or center-to-center distances have been shown for various building heights. Sizes are for internal columns, expressed in square inches. Peripheral and corner columns will be smaller.

The smallest dimension per side considered acceptable for concrete columns is 10 in., and 4 ft is the limit which normal concrete framework can easily accommodate. Columns with larger dimensions become, in effect, walls and are formed differently.

It is significant to note from the chart that an internal column in a tall building may be on the order of 2 by 3 ft. Such a planning element cannot be overlooked even for preliminary sketching.

Systems Approach

Any discussion of structural considerations in conjunction with housing must recognize that the housing industry appears to be at the beginning of an era of greatly increased prefabrication, which is leading towards full systems building and industrialization of the building process.

Residential APARTMENTS

Fig. 12 Concrete-column sizing guide. (Data supplied by Farkas Baron and Partners.)

Prefabrication and systems building has been applied widely in European countries for a number of years, and there have been many prototypical developments and limited applications of techniques in this field in the United States.

It is anticipated that, within the foreseeable future, virtually all European housing will be the product of some type of system. It would appear inevitable that progress toward industrialized construction will likewise continue in the United States.

At what precise point the utilization of systems building will become a major consideration in apartment design and what system or systems will survive to become a standard of the future is uncertain; however, it is a significantly growing field which will be watched closely by practitioners in the housing field.

Of the number of systems which are presently available, the following categories may be drawn:

1. Steel or concrete frame with precast planks, self-formed concrete deck or metal deck
2. Poured-in-place concrete tiers utilizing special reusable forms for transverse walls or columns
3. Long-span or short-span precast panel/plank and bearing wall
4. Prefabricated floor-size truss or beam systems with clear span capabilities.
5. Preamsembled modules, prepared off site or on site, for stacking or insertion in a structural frame

Figure 13 shows a composite structure including the categories described.

Any proposal to use a building system should be preceded by a thorough investigation as to availability, code and market accepta-

bility, union acceptability, adaptability to minor variations, and guarantees regarding erected costs.

VERTICAL SERVICES

Elevators

Figure 14 may serve as a preliminary guide in determining number and type of elevators necessary for an efficient solution.

There are four variables involved in elevator selection:

1. Travel distance
2. Elevator speed
3. Elevator capacity
4. Building population

Travel distance is represented on the graph as "Number of stories" based on the assumption of normal floor-to-floor heights.

Possible speeds for buildings of different heights are shown.

Building population is represented on the graph as "population per floor," with curves shown for typical floor populations. In determining population, two persons per bedroom are assumed.

Egress and Safety

Except in rare circumstances, relatively little in the realm of egress and safety is left to the discretion of the architect. In general, the architect may choose only among accepted and approved procedures as set down in codes.

In most codes, two means of egress must be provided within specified distances from each dwelling unit (Fig. 15a-c) except in the case of duplexes, which frequently require an additional means of egress off the corridors, usually by means of an escape balcony (Fig. 15e).

Figure 15d diagrams a scissor stair which, as shown, is an arrangement which allows for construction of two stairs in one fire enclosure. This is an efficient and cost-saving solution to the two egress requirements. Most codes, however, effectively preclude the use of scissor stairs, in many cases by limiting the allowable length of dead-end corridors. Fire escapes are usually required for construction that is not fireproof; and sprinklers, smoke doors, fire detectors, and alarms are additionally required for various classifications of construction in some codes.

Plumbing

Vertical plumbing risers and waste lines (or "plumbing stacks") are expensive due to both material and labor costs. Reduction in the number of stacks saves money and is, therefore, to a greater or lesser extent advantageous and advisable.

Fig. 13 "Systems" composite.

Fig. 14 Elevator guide.

Reduction in the number of plumbing stacks is accomplished by doubling or even tripling up on each stack at each floor. Figure 16 shows common bathroom and/or kitchen layouts with order-of-magnitude dimensions shown.

These dimensions, it should be remembered, are for rough layout purposes only and should be verified by consultants.

Ventilation

Interior spaces such as bathrooms, interior kitchens, and public halls require mechanical exhausting. Figures 17 and 18 may be used as guides, in making preliminary layouts, to determine the floor area to be allocated to exhaust ducts. Figure 18 indicates the area of exhaust and Fig. 17 shows buildup of fireproofing and

finish around the area of exhaust. The ratio of dimensions should be as close to square as possible and should not exceed a ratio of 3:1.

A mechanical engineer should be consulted to determine final data regarding size and location of ducts.

Heating and Cooling

In most cases, planning and spatial layout are not significantly influenced by heating and/or cooling units and their lines of supply. The most common exception is the case in which ducts deliver conditioned air from either a central source or a unit in the apartment. In such a case, ducts may be of such size as to become a planning factor. Otherwise, heating or cooling units are served either by hot and/or chilled

water pipes or electric conduit. Pipe risers as shown in Fig. 19 occupy a space of approximately 3 to 4 sq ft, are located at an outside wall, and generally, if possible, "run out" in two directions to serve two units at each floor. It is desirable to avoid having a common riser between separate apartments.

DETERMINATION OF A TYPICAL FLOOR

General

In discussing determination of a typical floor and specific apartment layouts, the most common structural type—poured-in-place flat-plate concrete construction with repetitive typical floors—is assumed. The principles of the pro-

Fig. 15 Types of stairs.

Residential
APARTMENTS

Fig. 16 Plumbing chases.

Fig. 17 Exhaust duct.

Fig. 18 Exhaust-duct sizing guide.

Fig. 19 Heating-cooling composite.

Fig. 20 Plan of 44-story apartment building with hatched areas indicating space devoted to vertical service elements.

Fig. 21 Typical floor.

(1) It is generally desirable to group vertical services such as the elevator, incinerator or refuse chute, flue, stand-pipe, and, if possible, stairs so as to minimize above-roof construction. (2) Stairs may be spaced to avoid corridors with lengthy dead ends. (3) Efficiency apartments, probably with higher-than-average late-night traffic, may be best located near the elevator. (4) Multibedroom apartments are best located at corners. Larger multibedroom units lay out more compactly with two exposures. Larger apartments at corners also can cut down on required public corridor. (5) An attempt should be made to back up similar units, such as bedrooms, as well as similar mechanical services. (6) It may be necessary to allow space for electric closets (i.e., electric distribution panels) at every sixth or eighth floor. If electric heat is used, closets may occur more frequently. (7) Community balcony, laundry, vending machines, pram storage, or tenant storage may be provided at each floor or only on certain floors. (8) A janitor's closet is usually located on each floor at the refuse room. (9) If the corridor has no window, mechanical ventilation is indicated. Delivery and exhaust ducts should be planned to be remote from one another.

cedure which will be outlined may, however, be applied to any construction technique or system, bearing in mind the unique characteristics of that technique or system. (See Fig. 20.)

Procedure

Sequentially, the steps in the determination of a typical floor (in an ideal case) could proceed as follows: (See also Fig. 21.)

1. Investigate program with regard to the total number and types of apartments.

2. Identify repetitive groups with each group possibly representing a typical floor.

3. Assign area figures to apartments as determined in program analysis or as required by governmental agency standards. Total up the area of the apartments in a repetitive group and to this total add 10 to 15 percent for corridors and cores. This figure then may represent the area of a typical floor. If the area figure is reasonable and economical, if the size of the building thus generated conforms with various limits of the site, and if the typical floor area is otherwise acceptable, the investigation may proceed.

4. Tentative acceptance of a typical floor fixes a total number of floors. The implications of this number with regard to the potential for efficient utilization of the various mechanical systems, soil-bearing characteristics, zoning limits, etc., should be investigated. If the number of floors checks out acceptably, actual planning and layout may proceed.

5. The typical floor distribution must now be accommodated within the tentatively accepted area and within reasonable dimensions. The elevator core and stairs should be located and apartments laid out around them.

Figure 22 diagrams interrelationships among component elements of a typical living unit.

Although many apartments tend to have much the same layout as the diagram, there are many alternative arrangements which retain the essential component relationships. Apartments may be arranged as corner or floor-through units and—in addition to flats, or apartments on one level—layouts may be on two or three floors or on split levels (see Fig. 23).

As the diagram indicates, it is considered desirable to have ready circulation from the entrance foyer to the activity elements of the kitchen, living room, and sleeping areas and at the same time to maintain degrees of separation among these three elements.

Ideally, each space in an apartment should have access or exposure to the outdoors. However, application of this principle could result in an excessively expensive building type. Therefore baths, foyers, and frequently kitchens and dining areas are usually developed as interior spaces (see Fig. 24).

FIRST-FLOOR ORGANIZATION

General

The first floor of an apartment building fulfills a number of different program requirements. It serves as a connection between the dwelling portion of a building and the outdoors; it relates and interacts with both the outdoor functions and the dwelling units; and, further, it accommodates the physical transition between the dwelling units and the first floor.

Figure 25 illustrates possible interrelationships of first-floor functions with both the outdoors and the dwelling units.

Program requirements for typical first-floor spaces frequently call for larger unobstructed areas than occur at dwelling floors above. Common methods employed to achieve the unobstructed space at the first floor are (1) to "push out" the walls at the ground floor and enclose a larger space with an appropriate structure or, (2) to hang a ceiling in the first floor and "collect" and redirect various vertical services which would otherwise break up space at the ground floor. This is a common method used in the case of plumbing, heating,

Fig. 22 Apartment element diagram.

APARTMENTS

TYPICAL DOUBLE-LOADED FLAT

THRU FLAT

CORNER FLAT

THRU DUPLEX

Fig. 23 Typical apartment types.

Fig. 24 Typical apartment layout.

(1) It is advisable to back up similar (kitchen and kitchen, bath and bath) ducts where possible. This allows one fan and fireproof enclosure to serve two ducts but requires measures to avoid excessive sound transmission between backed up spaces. Ducts may be "buried" in closets, kitchen, etc. Kitchen exhausts are best located near the range and close to the ceiling. Bathroom exhausts should, if possible, be placed away from the door in order to pull as much bathroom air as possible. Ducts are not necessary in kitchens or baths with windows (however, baths with windows, like top-floor baths, should be heated). (2) The structure should be spaced as regularly as practicable and within economical center-to-center distances. Columns built into closets or kitchens should assume the dimensions of the closet or cabinet. Column size should be reduced at upper stories of tall buildings. Slab openings along an entire column face should be avoided. (3) Plumbing backup is recommended. Dissimilar uses may be backed up, and it is possible to back up plumbing for more than two spaces. (4) Depth of rooms is sometimes limited by building codes. In any event, room depth relative to window size and location and natural light should be considered.

and electrical lines and not unusual for ventilating ducts. If there is substantial advantage to be gained, structural columns may be picked up and carried on girders concealed by the hung ceiling.

Vertical Circulation Core

For purposes of security and convenience, elevators should be well illuminated and visible from the lobby area. At least one exit stair should empty directly to the outside (but not necessarily at the lobby level).

It should be borne in mind that the stair layout in the lobby will frequently differ from a typical floor due to a greater first-floor ceiling height.

Mail Room

Mailboxes as well should be highly visible. If boxes are rear-loading, a locked room behind the boxes should be provided for the mailman's

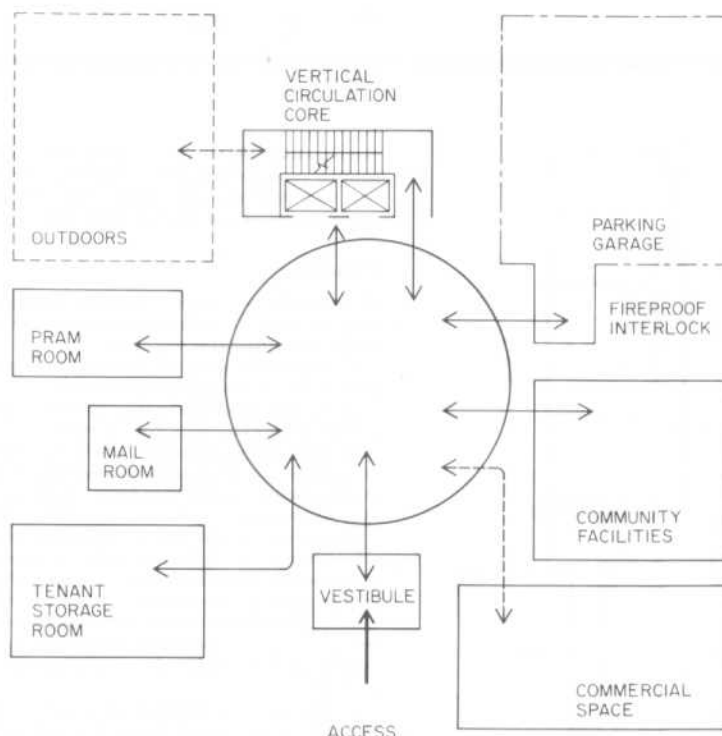

Fig. 25 First-floor diagram.

use. Front-loading boxes require no such room. However, in either case, an additional secure area for packages and deliveries may be advised. Current federal requirements which govern matters such as maximum and minimum height of boxes and size of mail rooms should be consulted.

Wheeled Storage and/or Pram Room

Paths of travel from the main entrance to these areas should be short, direct, and without steps. Layout of the rooms for purposes of security should be such that all parts of the room are visible from the entrance. Lock rails, to which equipment may be secured, should be supplied.

Commercial

Shops and service facilities at the ground floor provide many advantages in terms of activity and convenience. However, much of the advantage to the building may be diminished if

the shops face away from the lobby and provide either no access or poor back-door access from the apartment building itself. On the other hand, easy circulation between a commercial establishment and the lobby may cause security problems which must be considered.

Laundry and Community Room

Laundries and community rooms are frequently found at the first floor for convenient servicing and public access and in order to utilize the additional story height. These facilities should be on a short, direct path from elevators, with as little cross circulation with other activities as possible. (See Figs. 26 to 30.)

Laundries may be located either on typical floors or in a penthouse in conjunction with the community room.

Location of laundry rooms on typical floors has the advantage of convenience which, however, is offset by difficulties of multiple maintenance and problems of odor and noise.

Residential APARTMENTS

Fig. 28 Compactor room layout.

Fig. 29 Typical refuse containers. Consult and coordinate with refuse collection agency to assure acceptability of system regarding weight and size of containers, etc.

IT IS GENERALLY RECOMMENDED TO ALLOW RESERVE BOILER CAPACITY IN CASE OF BREAKDOWN

BREECHING FROM BOILERS TO FLUE, AS CLOSE TO SQUARE AS POSSIBLE, NO GREATER THAN 2:1 RATIO RECOMMENDED. AREA AND SHAPE SAME AS NET FLUE AREA.

OVERALL HEADROOM REQUIRED IN A TYPICAL BOILER ROOM MAY BE AS MUCH AS 2 OR 3 RESIDENTIAL FLOORS

Fig. 30 Boiler room layout.

A rooftop location for either of these facilities provides an additional level of amenity; however, it also involves additional expense.

Refuse disposal may be handled in a number of ways. The most widely used methods are by incineration or preferably, by compaction, with the processed refuse hauled away by truck. Both the incinerator and compactor require a storage area for waste containers, which should be nearby and should have easy access to the outdoors. The size of the container storage area will depend upon the type of container employed, frequency of collection, and, in some cases, agency standards. The area required for the refuse chute at typical floors is relatively small, ranging from 4 by 4 ft up to any size desired. The area of the compactor room or incinerator room at a lower level is quite large, and the refuse chute at the typical floor should be located so as to avoid interference problems at the lower levels.

HOUSING FOR THE ELDERLY

By W. RUSSEL PARKER, Architect

BACKGROUND

In the coming years, a greater proportion of houses, apartments, and institutional accommodations will be built for elderly persons than at any previous time in our history. There are several reasons for this. First is the well-known fact that the life-span of mankind has increased through advances in medical science; thus the proportion of older people in the population has increased. Second, with the passing of the three-generation household, more elderly persons are living by themselves and therefore require separate housing accommodations. Third, increased social security benefits and private pension payments have enabled more aged people to pay for suitable accommodations. Finally, many nonprofit groups such as church, labor, and fraternal organizations, charitably supported groups, and tax-supported bodies are, and will continue to be, engaged in the provision of housing specifically for the elderly.

Ordinary design criteria do not always apply to housing for the aged. One of the most striking differences is the high concentration of one- and two-person families as a result of children leaving home or the death of one spouse. Also important are the needs caused by physical deterioration in old age, which requires special design treatments and facilities.

In addition, certain basic psychological and sociological principles should be observed in planning for the elderly. People in this age group usually do not want to break their ties with family and neighborhood and be placed in a new and foreign environment. They need activities, not merely hobbies, and they want to participate in community functions. The objectives, programs, and physical facilities for the housing of the aged should encourage and support the continuance of earlier patterns of living, daily routines, personal care habits, social contacts, and recreational activities. An important objective is to maintain independent living as long as possible.

NEIGHBORHOOD AND SITE

A desirable neighborhood for the elderly should have many of the characteristics of any good neighborhood. It should be basically residential, possess the normal range of community facilities, have convenient public transportation, and be removed from particularly objectionable land uses. In terms of the individual aged person, the ideal neighborhood is often the one in which he has lived most of his life. The development of a broad program and the selection of a particular site should give consideration to old established neighborhoods where many of the aged are likely to be living and to have their roots.

From the point of view of the community

Multi-Unit Retirement Housing for Rural Areas—A Guide to Design Considerations for Architects, Engineers, and Builders, Agricultural Engineering Research Division, Agricultural Research Service, U.S. Department of Agriculture, Washington, D.C., 1965.

itself, there are also many advantages in housing the aged in well-established neighborhoods, where there are more existing facilities and generally better public transportation. Another advantage, which is frequently overlooked, is the sympathy and help that are extended to the aged by friends and neighbors, young and old alike.

The selection of an actual site involves the following considerations:

1. The topography should be as level as possible to minimize the need for steep walks, ramps, or stairs. Relatively level sites encourage walking—a highly desirable exercise.

2. The site should not be bounded on all sides by major traffic arteries. It should be possible to go shopping or to the park without having to cross a major street.

3. Essential commercial facilities should be close at hand and easily accessible—supermarkets, cleaners, laundries, shoe repair shops, drug stores, and the like.

4. Basic community facilities such as churches, libraries, health services, and recreation facilities should also be close at hand. In this connection it should be noted that a half-mile is the maximum walking radius of many aged persons.¹

5. Public transportation should be immediately available at the site, since many of the services that the aged require, such as specialized medical attention, will in all likelihood be located elsewhere. Transportation is also important for obtaining part-time work, for visiting distant relatives or friends, and generally for maintaining a spirit of self-sufficiency.

6. The site should not be immediately adjacent to a school building or a children's playground, or an active recreation area used by teenagers or adults.

7. The site should be large enough to permit the development of adequate outdoor areas for both active and passive recreation. Ideally,

¹Most aged persons place great emphasis on the proximity of essential services and facilities such as shops. In one study (Scottish Housing Advisory Committee, Housing of Special Groups, Edinburgh: H.M.S.O. 1952), approximately 90 percent of the aged persons surveyed considered proximity to shops essential. The other facilities desired were, in order: churches, 65 percent; parks, 50 percent; social centers, 37 percent; movies, 30 percent; and active recreation areas, 25 percent.

these areas would be in addition to, and out of the way of, those areas used by other residents, particularly children.

8. Consideration should also be given to possible changes in the over-all land use pattern, in terms of probable trends and projected plans.

These considerations must be taken into account whether the site is to accommodate solely aged persons or whether the aged represent only a portion of a larger "project" population.

DESIGN AND PLANNING PRINCIPLES

In very general terms the criteria for planning housing accommodations for the aged are:

1. Small size and compactness for convenience and economy

2. Fireproof construction planned for maximum safety

3. Minimizing of the problems and effort of housekeeping and daily activities

4. "Livability," pleasantness, and the effect of spaciousness

5. A high degree of privacy

6. Careful avoidance of an institutional look.

Other criteria affecting the different functional areas of the dwelling are discussed briefly in the following paragraphs. Many states have established official standards dealing with minimum areas, design features, etc., for housing for the aged (see Table 1). Before proceeding with specific designs, such local standards, if any, should be consulted.

Leisure Areas

Because the aged are generally retired, a comfortable and pleasant living area is highly important. Particular pains should be taken in the design of these spaces because they are not only intensively used but also tend to be quite small. Some suggested state standards, for example, call for living areas of 80 to 90 sq ft for single-person occupancy. Interesting views and southern exposure should be provided if possible. Extra-wide window stools for plants and built-in shelves and storage spaces are desirable. Privacy from the front door should be provided. If a dining area is included as a part of the living area, it should permit lo-

TABLE 1 Room Areas for Various Types of Housing Accommodations

No. of persons	No. of rooms	Types of rooms	Room area, sq ft					Total area
			Bedroom (B)	Living room (L)	Dining (D)	Kitchen (K)	Bath	
1	4	B,L,D,K	100	80-90	40	50	50	320-330

1	2	B,L-D,K	180		90		50	320
1	2	B,L-D,K		175-200		45-50	35-40	255-290
2	3	B,L-D,K	130-140	150	75-90		40-50	355-430
2	3	B,L-D,K	125-130	155-190		50	40-50	370-420

Data in this table have been compiled from various state regulations and recommendations.

HOUSING FOR THE ELDERLY

cation of the table by a window. A light and/or a convenience outlet should be easily accessible to the table.

Sleeping Areas

A separate bedroom is necessary for two-person occupancy, but a sleeping alcove or a combined living-sleeping arrangement is often satisfactory for single persons. The separate bedroom should always be large enough to accommodate twin beds, and it is often desirable to be able to divide the room in two with a screen. (See Figs. 1 to 4.)

Fig. 1

A combined living-sleeping arrangement is the most economical in terms of space but has the disadvantages of lack of privacy and a tendency to be untidy. The sleeping alcove is a generally satisfactory compromise, since it offers almost the same economy as the combined arrangement but without its drawbacks. The alcove should be large enough to accommodate all the essential items of any sleeping area—bed, night table, storage chest, closet, and chair—and it should be possible to close off this area from the living area if desired. There should always be an operable window in the alcove for light and ventilation.

Fig. 2

Regardless of which arrangement is used, certain details should receive attention:

Adequate space should be provided in bedrooms for getting into bed from either side, making the bed, using the dresser or chest of drawers, cleaning the room, using the closet, and dressing. In the sketches (Figs. 1-5), the recommended amount of space for these activities is given.

To provide for this degree of comfort and convenience, the bedroom must be about 11 ft 2 in. wide and 9 ft 10 in. or 10 ft 4 in. long, depending on whether space is provided at the

Fig. 3

"Limited space" allows space to open closet door and remove garment. "Liberal space" allows space to open closet door, remove garment, and put it on.

foot of the bed for dressing or just for opening the closet door. If twin beds are to be used, the width of the room (with the furniture arranged as shown) would need to be increased to 15 ft. This would give space for two twin beds, each 39 in. wide, with 22 in. between them. (See Fig. 5.)

Fig. 4

In the case of two-person occupancy, whenever more space is available, 3 ft is often recommended as the clear distance between beds, and some agencies recommend an allowance of at least 5 ft at one side of the bed for a wheelchair.

- Whenever possible, there should also be space for an oversize bedside table to hold medicines, water, tissues, and the like in large quantities.

- The plan should permit placement of the bed so that a bedridden person can see out the window.

- It is often desirable to provide a bell or buzzer near the bed so that a person can summon assistance.

- In close proximity to the bed there should be a convenience outlet which is hooked up

Fig. 5

with a switch at the door or the entrance to the space. Thus a bed lamp could serve as the essential nightlight. Because of the two-way switching possible, this arrangement is preferable to the use of a single-switch ceiling or wall fixture.

- There must be a short and direct access from the bed to the bathroom.

BATHROOMS

Bathrooms for older people should be ample in size and planned for safety. Many of the elderly need assistance in the bathroom, so the room should be large enough to permit one person to help another. For a person in a wheelchair, the bathroom should be large enough that he can maneuver the chair, and the doorway must be 3 ft wide.

The location of the bathroom in relation to the bedroom, as well as other rooms of the house, must be given special consideration. If possible, one should be able to get into the bathroom without having to go around furniture or through other rooms.

A minimum area of 35 to 40 sq ft is acceptable but, because of the possibility that crutches or wheelchairs may need to be accommodated, 50 to 60 sq ft is often recommended.

Bathrooms without windows are acceptable and have some advantages for the older person. Ventilation is easily controlled by a switch. In a bathroom with an outside wall and window, avoid—if possible—placing the bathtub under the window, because it is difficult to open the window and to clean and curtain it. But if that is the only possible location, then select a crank-type window.

A lavatory installed at a height of 33 in. is more comfortable to use than one installed at the customary 31-in. height. For a person in a wheelchair, however, the 31-in. height is better. Lavatories should be well-supported, to hold a person's weight.

The shower and tub faucets should be placed so that a person can reach them easily both before and after stepping into the tub. Showers should have mixing controls, preferably thermostatic, and it would be well to have a testing spout where the mixture of hot and cold water could be tested for showers and tub baths. Design shower stalls without curbs, using a sliding door or other firmly installed and safe closure, and a seat, either built-in or removable, is desirable for both tub and shower. The tub should have a low side and flat, non-slip bottom.

The toilet should be placed next to the tub (if a tub is used) so it can be used as a seat when filling the tub or simply for resting, and grab bars should be provided at the toilet and tub or shower.

All grab bars and hand holds should be of noncorrosive material, $\frac{3}{4}$ to 1 in. in diameter, and mounted to withstand a pull of at least 500 lb.

Towel racks and rods should also be strong and securely mounted because older people sometimes use them as grab bars to steady themselves. Glass towel rods should not be used.

Medicine cabinets should be extra large and preferably recessed. Projecting accessories should be avoided whenever possible. It should be possible to unlock the door from the outside in an emergency.

Bathroom Arrangements

Figures 6 and 7 are suggested arrangements for bathrooms with tubs and shower stalls. The

HOUSING FOR THE ELDERLY

Fig. 6 Bathrooms with tubs.

star indicates where space has been provided for a helper.

KITCHEN

Because kitchens are potentially as dangerous as bathrooms, equal care should be given to their layout and design. In locating the kitchen in the plan, provide easy access to the outside and direct access to the dining space, which could be a portion of the living room. In some plans, space can be provided in the kitchens for dining. In these cases, however, an additional 20 to 40 sq ft are necessary. Interior locations are acceptable if mechanical ventilation is provided.

Do not plan extremely compact kitchens for older people; they desire and need ample work space. If the kitchen is too compact, storage space is limited and much of it is either too high or too low to be reached comfortably. Shelves should be no higher than 68 in. from

the floor, and no lower than 12 in. Too little counter space leads to crowded work surfaces, which in turn can create hazardous working conditions.

Clearance between facing equipment and counters should be a minimum of 3 ft for one person. To permit two people to work and pass each other, the between-counter clearance should be 4½ ft.

Equipment should be electric for greatest safety and should be arranged for maximum efficiency. Ranges should be provided with front rather than back controls. Heating elements should visibly glow when hot. In placing the range, consider allowing extra space for ease in making minor repairs and cleaning. A wall oven set at waist height is desirable. Although refrigerators need not be larger than a 6 or 7 cu ft capacity, they should have a large freezing compartment and should be self-defrosting. Do not place the refrigerator too low—as under a counter. In choosing the con-

ventional type of refrigerator, consider the amount of stooping and reaching that will be necessary.

Double sinks or sink-and-tray combinations should be provided to facilitate hand laundering. Consideration should be given to the provision of complete laundry facilities, particularly in projects. If full laundry facilities are not possible, at least drying racks should be provided.

Storage spaces should be arranged as nearly as possible so that the bulk of the regular-use items can be stored between 27 and 63 in. from the floor. Ideally, stored items should be visible as well as physically accessible. Storage spaces over ranges and refrigerators should be avoided. Sliding cabinet doors are preferable to swinging doors.

Provide adequate lighting over all work surfaces; provide an exhaust fan to assure adequate ventilation and to carry out cooking odors; select floors or floor coverings that will

Fig. 7 Bathrooms with showers.

HOUSING FOR THE ELDERLY

Fig. 8 U-shaped kitchen cabinets.

not absorb grease and become slippery; and provide a fire extinguisher for grease and electric fires. (See Figs. 8 to 11.)

DINING AREAS

The size of the dining space needed is determined by the number of people to be served; furniture including table, chairs, buffet, cabinet, and serving table; and the amount of clearance required for passage and serving.

Allow 21 to 24 in. of table space for each person. The minimum-size table at which eight adults can sit comfortably, three on each side and one at each end, is 40 in. by 72 in. The minimum size for six adults with two on each side and one at each end is 36 in. by 60 in. A round table 42 in. in diameter is minimum for four people, and 48 in. for six people.

Regardless of the size or shape of the dining table, certain minimum clearances around it should be provided. Allow 36 in. between the wall or a piece of furniture and the table in order to edge past a seated person. Serving requires 44 in. from table to wall; 32 in. is needed for rising from a chair at the table. (See Fig. 12.)

Fig. 9 Parallel wall with wall oven.

General Storage

Ample, lighted closets should be provided for clothes, linens, and miscellaneous household items. Closets should either have sliding doors or be arranged for the use of curtains or screens. Provision must also be made for general storage of bulky items, such as trunks and furniture.

CONSTRUCTION, EQUIPMENT, AND FURNISHINGS

In designing housing for the aged, special consideration must also be given to the selection of materials, hardware, and equipment.

Fig. 10 L-shaped, showing recommended widths and clearances.

Some criteria that should govern the selection of these items are presented below.

Floors

All floor surfaces should be nonslip, outside as well as inside the basic dwelling unit. In this connection, apparent slipperiness is as important, because of the psychological danger, as actual slipperiness. This is particularly pertinent to the design of lobbies and other public spaces which often have large expanses of glossy, although perhaps nonslip, surface. Suitable flooring materials include unglazed tile, cork, vinyl or vinyl-asbestos tile, unwaxed wood, and wall-to-wall carpeting. Throw rugs or deep-pile rugs are generally unsatisfactory because of the danger of tripping. Unwaxed wood floors are particularly satisfactory for the wheelchair user. Floors should be smooth and level, and particular care should be taken with highly jointed materials such as ceramic tile or brick or stone. Door thresholds and minor changes in floor level should be avoided whenever possible.

Doors and Hardware

Door openings should be 3 ft wide to permit easy passage of wheelchairs, stretchers, and persons using crutches. Precautions should be taken to see that doors fit properly and do not stick, and thresholds should be eliminated. Bathroom doors should not have locks; provide easy latches instead. Large, easy-to-grasp doorknobs or lever-type handles should be used. Revolving and double-acting doors and automatic door closers are particularly dangerous and should be avoided. In projects, outside doors should be master-keyed and all devices which cannot be operated from the outside should be prohibited. It is also desirable to

Fig. 11 Cabinet heights.

provide peepholes or vision panels. Sliding doors conserve valuable space in small units and eliminate the danger of walking into half-open doors.

Windows

Whenever possible, windows should look out on an interesting view. In housing for older people, the height of the windows is important, particularly in the living room, dining area, and bedroom. Sitting and looking out of the window is a daily activity for many of the elderly.

The living room windows should be low so that a person sitting in a lounge chair can see out. The bottom of the window should be no higher than 3 ft 2 in. from the floor and can be as low as 1 ft. For window walls, it is desirable to include a guard rail at a height that will not interfere with viewing but that will give a feeling of security. To permit viewing from a standing position, the window should extend to a height of 6 ft. 8 in. (See Fig. 13.)

For dining areas, the eye-level zone is determined by the sitting height. The sill of the window can be 2 ft 6 in. from the floor. For the bathroom and kitchen, the eye-level zone is set by the standing height. The opening of the window should be between 3 ft 6 in. and 6 ft 8 in. from the floor. (See Figs. 14 and 15.)

For bedrooms, one window should be low enough to permit a person in bed to look out. In addition to making the room more pleasant, a low window provides an emergency exit. The eye-level zone suggested for the dining area could also apply to bedrooms. Window arrangements that produce a uniform distribution of light are preferable to a spotty placement of openings.

Choose windows that are easily operated. Except for over the bathtub and similar locations, double-hung windows are satisfactory. But in hard-to-reach places, windows that are opened and closed by turning a crank are easier to operate. Many windows have been designed to reverse so that the exterior side of the glass can be turned to be washed from the inside. This is an important safety factor for those who find it difficult to reach or climb. Insect screens, weather stripping, and storm sash should be provided for all windows depending upon the location and climate.

A southerly orientation is most desirable, but provision should be made for shading devices. Roller shades should be avoided because of the danger involved in retrieving a released shade. Venetian blinds or draw-type draperies are preferable.

Lighting

Illumination levels should be approximately double those generally used in residential

HOUSING FOR THE ELDERLY

Fig. 12

practice. Light sources should always be shielded. Ceiling-mounted fixtures are not recommended because of the dangers inherent in cleaning the fixtures and changing bulbs. As indicated earlier, it is highly desirable to plan lighting layouts so that lights can always be switched on from a doorway. Wall switches should control all light fixtures. Switched outlets are particularly important in bedrooms or sleeping alcoves so that the elderly person need not stumble around in the dark when looking for the switch or after turning off the light.

Place a convenience outlet for use of a night-light between bed and bath. A night-light in a central location is often useful, as are luminous switch plates. Convenience outlets should never be located less than 18 in. above the floor (30 to 40 in. above the floor is preferable).

Have the entrance well lighted so that steps (if any) can be clearly seen and keyholes can be located.

Heating

The aged generally require a higher temperature level than the standard: approximately 80°F. The heating system should be quick-acting and arranged to provide a uniform distribution of heat. If the aged are to be housed in structures with younger occupants, consideration should be given to the provision of separate temperature controls or supplementary heat sources. If steam or hot water systems are used, exposed radiators and risers should be avoided. Exposed radiators under operable windows are particularly hazardous. Although cold floors are to be avoided, radiant panel floors seem to be undesirable because they aggravate conditions of impaired blood circulation in the legs.

Sound Control

While a certain degree of acoustical privacy is necessary in any building, it is perhaps more important in housing for the aged than in other residential work. There is a strong desire on the part of the aged to protect their privacy and to be assured of quiet during their rest periods and in the event of illness. Elderly occupants tend to be especially sensitive to the noise of children.

Communications and Alarm Systems

In any building devoted exclusively to housing the aged, an automatic fire alarm system should be provided. Because of the difficulties many elderly persons experience in bedrooms and bathrooms, particularly at night, it is desirable to provide some form of signaling device whereby they can summon help. Usually the device sounds in a neighboring apartment or in a resident manager's or superintendent's

suite. In buildings or projects devoted exclusively to the aged, it may also be desirable to provide a conveniently located public telephone booth, since many aged cannot afford a private telephone. When installed in the dwelling, however, locate a telephone conveniently near the bed. Several outlets would be most helpful.

Vertical Circulation

Whenever possible, accommodations for the aged should be on one level and, unless elevators are used, located on the ground floor. In the case of low buildings where elevators are uneconomical, the aged should not be expected to climb more than one flight. For small unavoidable changes in level, ramps with flat slope not over 5 percent are preferable to stairs. Where stairs must be used, the following precautions should be observed:

1. Risers should not be more than 7 in. high.
2. The proper proportion of run to rise should be scrupulously observed.
3. Fewer than two risers should be avoided.
4. Winders or curved treads should never be used.
5. Non-slip nosings should be used and should be of a contrasting color.

6. Continuous handrails should be provided on both sides of the stairs.

7. Handrails should be of the proper height, of a cross section which is easily grasped, and sturdy in appearance as well as in fact.

8. Stairs should not be less than 3 ft 3 in. in clear width.

9. No doors should open directly onto the stairs.

10. Traffic should not cross the top or bottom of the stairs.

11. The stairs should be well lighted with shielded sources.

Some special considerations should also be observed with respect to elevators:

1. Self-operated elevators should be equipped with automatic doors.
2. A signaling device should be provided to summon assistance.
3. Continuous handrails should be provided, and if the car is sufficiently large, a small bench should be considered.
4. An automatic leveling device is necessary and should be inspected frequently.
5. If there is a possibility of use by a disabled person in a wheelchair, the control panel should be mounted low enough to be reached from a sitting position.

Fig. 13 Eye-level zone for living rooms.

Fig. 14 Eye-level zone for dining areas.

Fig. 15 Eye-level for kitchens and bathrooms.

HOUSING FOR THE ELDERLY

ENTRY/EXIT*

The entry/exit (or front door) is the critical transfer point from the least public area of the development to the least private area of the dwelling unit. If properly designed, it will insure the privacy of unit activities and contribute strongly to the sense of home. It must be a place, not just a door in a wall which opens directly into the living area or other such space. (See Figs. 1 and 2.)

Accessibility The entry/exit area should be directly accessible to the following less private areas of the unit:

- Dining
- Living area, with spatial differentiation between the two functions
- Storage/utility

The entry/exit area should be indirectly accessible (minor intermediate activity or a circulation path) to more private areas of the unit:

- Dining
- Private outdoor (optional)
- Personal hygiene
- Sleeping/dressing

The entry/exit area should have both visual and audio contact with visitors outside of the entry door; but visitors should not have visual contact and only controlled audio contact into the entry area of the dwelling unit. This maximizes the ability of the resident to keep out unwanted visitors and allows the resident to control the space just outside the unit.

All of the previously mentioned spaces with direct physical access to the entry/exit area should have visual/audio contact with this area for control and security within the unit. Other areas should have audio but not visual contact to minimize disruption of privacy.

Orientation The orientation of this activity toward view and sunlight is governed by more essential concerns related to building type and the functional organization of other activities.

Furnishability The furnishings and equipment necessary for this area are:

Storage for outer wear, that is, coats, galoshes, umbrellas, etc.; a closet at least 3'-0" by 2'-2" should be provided

A place to sit while putting on outer wear

Spatial Characteristics The space should have sufficient wall area to accommodate a mirror; there should also be a clear dimension area of at least 3'-6" to 4'-0" square for putting on coats as well as greeting guests.

FOOD PREPARATION

The physical characteristics of the aged hamper the normal functions of food preparation, cooking, food and utensil storage, trash disposal, dish washing and drying, and eating. If appropriate physical design adaptation is not made to the food preparation space and facilities, cooking and related activities will become unpleasant, tedious, and possibly dangerous. The net effect will be the creation of a psychological barrier which deters the user from cooking and eating. This situation is particularly unacceptable because dietary problems can become acute for the aged.

Accessibility The food preparation area should be directly accessible to the main entry/exit of the dwelling unit to facilitate carrying of bundles. It should also be directly accessible to the dining area. If the dining area is outside of the kitchen, a small eating surface in the kitchen for breakfast or light meals should be provided. This can be a small table, counter, or pull-out shelf about

24 by 24 inches, set at table height and usable from a wheelchair. The food preparation area should be indirectly accessible to, but visually screened from the living, sleeping, personal hygiene, and private outdoor areas of the dwelling unit. Of these, access should be most direct to the private outdoor space. In all cases, indirect access should be through easily traversed intermediate spaces or corridors.

Visual and audio contact to the entry/exit area should be maintained, while audio contact to the living, sleeping, and personal hygiene areas should be minimized. (See Fig. 3.)

Orientation Often food preparation areas are located at the rear of dwelling units, but, where possible, this should be avoided. The kitchen should be located on an outside wall with an interesting view from a window and it should have morning sunlight if possible.

Furnishability and Equipment The necessary equipment for food preparation and related activities is:

- Ventilation, both mechanical and natural, to eliminate heat and odors
- Sinks and associated work space
- Cooking unit and oven with associated work space
- Refrigerator and freezer with associated loading and unloading counter space
- Storage consisting of wall and base cabinets and pantry
- Dishwasher, optional but should be included where possible
- Dining counter (where formal dining space is outside of the kitchen)
- Clothes washer and dryer; location in the unit is optional, but the kitchen is a good location when this option is exercised

Fig. 2 The foyer.

Fig. 1 Unit entry/exit.

Fig. 3 Kitchen area.

* Pages 92 to 101 from *Housing for the Elderly Development Process*, Michigan State Housing Development Authority, Lansing, Michigan, 1974.

HOUSING FOR THE ELDERLY

An example of a desirable organization of kitchen activities is shown in Fig. 4.

An L- or U-shaped kitchen is preferable to the pullman or corridor type kitchen. The corridor type is inconvenient for the elderly who, with advancing age and motor/sensory losses, find it difficult to repeatedly turn from one counter to another as they work. The table and Figs. 5-7 give necessary clearances and dimensions.

Equipment should be placed so that there is sufficient operating room between it and any adjacent corner cabinet. At least 12 inches from the edge of the sink and range and 15 inches at the side of the refrigerator are recommended.

A minimum of 42 inches should be provided between base cabinets or appliances opposite each other. This same minimum clearance applies when a wall, storage wall, or work table is opposite a base cabinet.

Desirable kitchen layouts and work area frontages are illustrated in Figs. 5-7. There should be no through circulation in the kitchen work area.

Spatial Characteristics To insure that this space is enjoyable to work in, it is necessary to provide adequate artificial light at all work areas and to create a spatial volume of appropriate scale. These criteria can be translated to mean that the ceiling height should be no lower than 7'-6". Color should be used carefully and be tied to visual identification. It should not create the impression of a closed-in, constricting place. Where ductless range hoods are used, another means of ventilation should be used to carry away cooking heat. Where main dining is combined with food preparation, there should be clear spatial distinction between them, perhaps even a difference in ceiling height.

DINING

There must be a permanent dining place within each dwelling unit for the independent elderly. Depending on the program, the space may be

eliminated from units which are part of formal congregate care programs. This place may be within or outside of the food preparation area. Secondary activities will naturally occur within this area such as table games, letter writing and paper work, and hobbies. (See Figs. 8 and 9.)

Accessibility Because of the array of activities that will be carried out, the dining area should have direct accessibility to:

- Food preparation, to facilitate serving of food and cleaning of dishes
- Living area

The dining area may have only indirect (minor intervening activity or circulation path) accessibility to:

- Entry/exit
- Private outdoor

These relationships should be subordinated to the requirements of relationship to the food preparation and living areas. There should be no direct accessibility between the dining activity and:

- Sleeping/dressing
- Personal hygiene

There should be direct visual/audio accessibility between the dining and the food preparation areas. Dependent upon unit organization, there may be direct visual/audio relationship between the dining and living areas; however, in such a case there should be no visual connection between the food preparation and living areas through the dining area. Visual/audio contact between the dining area and the very private areas such as sleeping/dressing and personal hygiene should be minimal or entirely eliminated.

Orientation Wherever possible, the dining area should have views out of the dwelling unit and should also have morning sunlight. Where the orientation is western, it is important to control the harsh effects of the setting sun. Because other

Frontages for Work Centers

Work centers	One bedroom	Two bedrooms
Sink	24"	24"
Counter and base cabinet at each side	18"	21"
Range	24"	24"
Counter and base cabinet at one side	18"	21"
Refrigerator (space)	30"	36"
Counter at latch side	15"	15"
Mixing		
Base and wall cabinet	30"	36"

Fig. 5 Minimum corner distances.

Fig. 6 Minimum frontages and edge distances—one bedroom.

Fig. 7 Minimum frontages and edge distances—two bedrooms.

HOUSING FOR THE ELDERLY

functional relationships must be achieved (such as entry/exit to the living and food preparation areas, and the food preparation area to the dining area) these orientation criteria must be subordinate and may not be achievable. At the very

least, views out should be possible through other activity areas.

Furnishability Each dining space must contain sufficient space to accommodate four people. It is desirable if sufficient space is available to expand this accommodation to six persons for special circumstances. Appropriate space should be provided for the storage of china and large dining articles. There should be space to accommodate the following items of furniture:

- Dining table with a minimum width of 3'-0", and 2'-0" of edge length for each diner (tables should be no less than 3'-0" by 3'-0" square, or 3'-6" in diameter)
- Dining chairs of 1'-6" by 1'-6" sufficient for the number of diners that can be accommodated
- Buffet or storage unit of 1'-6" by 3'-6"

Size of the individual eating space on the table should be based on a frontage of 24 inches and an area of approximately 2 square feet. In addition, table space should be large enough to accommodate serving dishes.

The following minimum clearances from the edge of the table should be provided:

- 36" for chairs plus access thereto
- 42" for chairs plus access and passage
- 42" for serving from behind chair
- 30" for passage only
- 48" from table to base cabinet (in kitchen)

In sizing a separate dining room, provision should be made for circulation through the room in addition to space for dining.

Spatial Characteristics As noted above, the dining activity space may be located separately or combined with living or food preparation spaces. Because of economic considerations, a separate dining space seems unlikely but, nevertheless, it is desirable that developments offer both arrangements to provide a variety and choice in responding to the differences between formal or informal lifestyles of various tenants.

The ceiling height of the dining space in a dwelling unit may be raised or lowered for spatial effect; it should, however, be no lower than 7'-6".

The dining table location should be permanent, requiring no rearrangement of furniture at meal-times, and use of this space should not infringe upon other activities. Wall area should be available for hanging pictures and the like. It should be possible to see the outdoors from the dining table.

Where cabinets are used to separate the food preparation area from the dining area, some of the cabinets should open from both sides to facilitate table setting.

GENERAL LIVING

Each dwelling unit shall have an area or areas which are organized and furnishable for a wide range of activities such as:

- Conversation
- Entertaining
- Reading
- Television viewing
- Radio/record listening
- Contemplation
- Lounging

In most units, more than one of these activities will be provided for in a single space. In larger than standard units or in two-bedroom units, however, it may be desirable to provide more specialized spaces.

Accessibility Direct physical accessibility (no intervening spaces) should be provided to:

- Entry/exit (planning can be too open; therefore, there should be a definite spatial distinction between living area and entry/exit)
- Private outdoor, for the extension of general living activities
- Dining, where these spaces are combined, accessibility should not impair either activity

Indirect physical accessibility (minor intervening activity or circulation path) should exist between:

- Food preparation
- Personal hygiene, for visitor use (this accessibility should not impair the privacy of the sleeping/dressing areas)
- Storage/utility
- Sleeping/dressing

Built-in table w/ 22" seating one side

Fig. 8 Minimum clearances for dining areas in kitchens.

(a)

(b)

Fig. 9 Minimum clearances for dining areas: (a) one end of table against wall; (b) serving from one end and one side of table

HOUSING FOR THE ELDERLY

Visual and audio contact with equally active areas (entry/exit and private outdoor) should be encouraged. Visual and audio contact to the food preparation area should be either minimized or controllable so that it can be minimized or maximized as desired by the resident. The visual/audio relationship between the dining and living areas will vary with the location of the dining area. Visual/audio contact to sleeping/dressing and personal hygiene spaces should be minimized.

Orientation Living spaces will be occupied many hours of the day and should, therefore, be provided with interesting views out of the unit. Windows should be located so that a seated person can see out. In first and second floor units, windows should also be carefully located to avoid loss of internal privacy from outside of the unit. On upper floors, close views from one unit to another should be avoided.

Fig. 10 Sun orientation.

Sunlight is important to both physical and mental conditions and, therefore, planning should insure that living spaces will receive some sunlight during each sunny day (probably no less than 30 percent of the day). Northern orientations should be avoided. Reference should be made to Fig. 10 for acceptable sun orientations.

Furnishability Furniture that should be accommodated in the living area should include the following items (sizes are minimums) for one-bedroom units:

- One couch, 3'-0" x 6'-10"
- Two easy chairs, 2'-6" x 3'-0"
- One television set, 1'-4" x 2'-8"
- One table, 1'-6" x 2'-6"

For two-bedroom units one easy chair should be added as well as:

- One desk, 1'-8" x 3'-6"
- One desk chair, 1'-6" x 1'-6"

Because of the diversity of activities which may occur in this space or spaces, and because provision must be made for a wide variety of lifestyles, special provision should be made in the design process to allow for many alternate furniture types and arrangements. The location of doors, windows, and other openings should be carefully considered so as not to unnecessarily limit furniture arrangement. A substantial amount of uninterrupted wall length is required. It should be remembered that many elderly residents will come from single-family or larger rental housing and many of them can be expected to have much more furniture than described above.

The following specific design criteria shall be used:

- 60" minimum clearance should be provided between facing seating.

- 30" minimum clearance is required for use of a desk.
- 60" minimum distance is necessary between the television set and seating. The designer should make sure that it is possible to locate the set opposite the main seating area.

People gather during social activities in rather small groups and a desirable conversation distance is rather short; an area approximately 10 feet in diameter is workable.

Figures 11-13 illustrate the desired circulation and furnishability requirements.

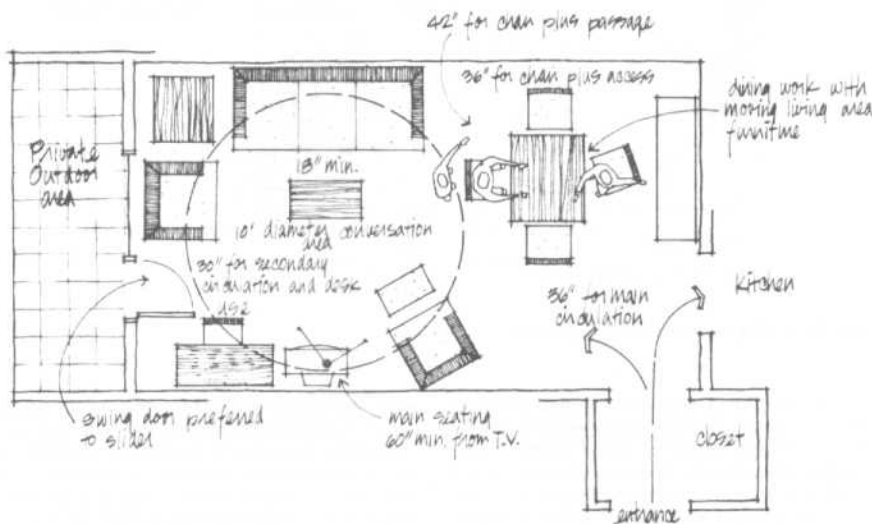

Fig. 11 Minimum clearances, circulation, and conversation areas for living rooms.

Fig. 12 Living room circulation approaches.

HOUSING FOR THE ELDERLY

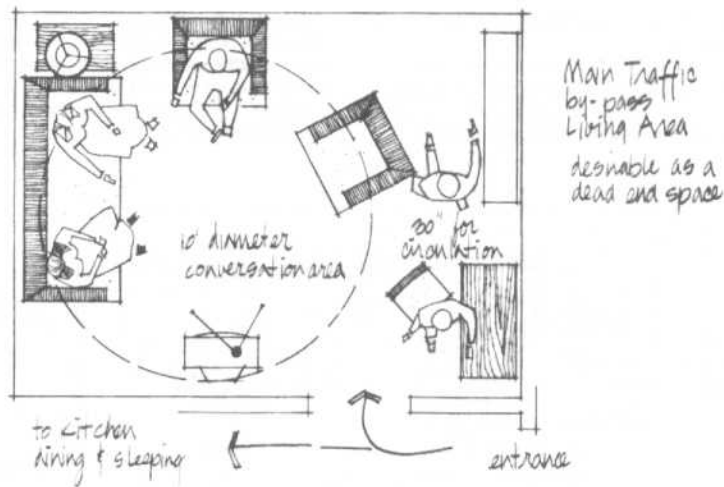

Fig. 13 Living room circulation approaches.

The living area or areas will most probably have to sustain both intra- and interspace circulation. Adequate circulation space which is direct and nondisruptive is important because of the tendency toward infirmity of movement and loss of visual acuity in the elderly. The following criteria pertain:

- 36" minimum clearance should be possible for main traffic paths. This dimension will also accommodate a wheelchair.
- 30" minimum clearance should be allowed where secondary circulation occurs between furniture.

Spatial Characteristics The living area is likely to become the focus of the dwelling unit for many residents. The size of the space, however, is often not as important as good planning which effectively accommodates the living activity while also accounting for circulation, doors, windows, and furniture. This does not mean, however, that a small space is desirable; in fact the living area should be of sufficient size as to allow some excess in floor area for such temporary activities as exercises, ironing in front of the television set, etc. Provision of floor area beyond the minimum space required by the furnishability test will also insure the accommodation of a wider range of lifestyles and activity patterns.

The living activities area may be greatly enhanced in spatial character by a higher than normal ceiling if the building type permits.

As a general rule, it has been found that a width of less than 12 feet is difficult to utilize effectively. It has also been found that rectangular rather than square space is easier to furnish and to zone for different activities.

Consideration should be given in dwelling units of larger than standard size to subdividing the living activities area into two separate areas such as a living room and den/sewing room combination. This can also be accommodated by room configurations (such as L-shape) which are easily subdivided by furniture arrangement. This approach is particularly effective where there are two residents in a unit who wish to carry on different activities simultaneously.

SLEEPING/DRESSING

The elderly make greater use of the bedroom than any other age group except babies. An effi-

cient and commodious bedroom is important for any household but for older people it is absolutely necessary. This is partly because of the need for rest periods but also, as people grow older, many become more susceptible to illness and are bedridden more frequently than younger people.

Accessibility This activity is one of the most private in the dwelling unit. In dwelling units containing two residents it is essential that one resident be able to carry on normal living activities (including entertaining visitors) without serious loss of privacy to the other person in the bedroom. Because of this basic need, direct physical accessibil-

ity (only minor intervening space) should only exist between the sleeping/dressing area and:

- Personal hygiene
- Personal clothing storage

The bathroom may also be accessible through a hall.

In some cases provision for personal living activities may be located within the bedroom. Direct accessibility to private outdoor space may also be acceptable under some circumstances.

Indirect accessibility (through intervening circulation) should exist to:

- Food preparation
- Storage/utility

No direct accessibility should exist between the sleeping/dressing area and:

- Entry/exit, for protection of privacy
- Living
- Dining

Because of the privacy factor and the desire to be able to entertain guests without having to make the whole dwelling unit tidy, the sleeping/dressing area should be isolated from most visual and audio contact with other areas in the dwelling unit. The level of visual/audio contact between the bathroom and the sleeping/dressing area should be controllable to insure bedroom privacy when a guest uses the bathroom. It is desirable that a circulation space serve as a buffer between the sleeping/dressing area and the rest of the dwelling unit.

Like the living area, this area should have excellent views from its windows. Windows should be placed so that a person can easily see out while lying in bed. This space requires direct exposure to the sun for at least 30 percent of the day. Reference should be made to Figs. 14 and 15 for desired sun orientation.

Furnishability In addition to the sleeping and dressing functions, the bedroom should have provisions for such passive living activities as:

- Television viewing
- Reading
- Sewing

The minimum furniture to be provided for is as follows:

- Two twin beds (3'-3" x 6'-6") or one double bed (4'-9" x 6'-6")
- One dresser (1'-6" x 4'-4")
- One chair (1'-6" x 1'-6")

Fig. 14 Sun orientation.

Fig. 15 Space orientation.

HOUSING FOR THE ELDERLY

One table (1'-6" x 2'-6") for sewing or other work (optional)
 Two night stands (1'-6" x 1'-6")
 One portable television set

Where both bedrooms of a dwelling unit are primary (as in unrelated occupancy), the above requirements apply to both.

Twin beds should be possible even in the bedroom of a unit programmed for single-person occupancy.

A secondary bedroom for single occupancy should have circulation space and accommodate furniture of the following sizes:

One twin bed (3'-3" x 6'-6")
 One dresser (1'-6" x 3'-6")
 One chair (1'-6" x 1'-6")
 One night stand (1'-6" x 1'-6")

The location of doors, windows, and closets should be planned to allow for the best placement of the bed and other furniture.

The closet should be placed next to the door into the bedroom because the use of available wall space is minimized in this way (Fig. 16).

For reasonable access to and use of bedroom furniture and equipment, the following minimum clearances should be observed:

42" at one side or foot of bed, for dressing
 24" clearance for least used side of double bed
 6" clearance from side of bed to side of dresser or chest of drawers
 36" clearance in front of dresser, closet, or chest of drawers
 30" clearance for major circulation path (door to closet, etc.)
 24" clearance between twin beds
 18" clearance between twin bed and wall for ease of bed making

It should not be necessary to move beds in order to make them up. Bedrooms should be sufficiently

large and so designed as to permit alternate arrangements of furniture if at all possible. There should also be space provided for working privately or resting. (See Figs. 17-19.)

PERSONAL HYGIENE

The bathroom is the subject of much public and private research. What is set forth here is not

ideal but rather an attempt to synthesize the most current thinking on the subject as it relates to the elderly user. In addition, requirements for adoption of bathroom facilities for use by permanently disabled persons are included. These requirements shall apply to at least 10 percent of the units in developments of 100 units or more. Application to smaller projects will be determined individually for each case.

Fig. 17 Typical standard bedroom—with twin beds.

Fig. 18 Typical standard bedroom—with double bed.

Fig. 16 Closet depths.

Fig. 19 Larger-than-standard bedroom—may be applicable in larger-than-standard unit or in two-bedroom unrelated occupancy.

HOUSING FOR THE ELDERLY

In general, bathrooms in developments for the elderly should be given great care in design as this space can, if poorly conceived, cause both serious health hazards and, through its inconvenience, great frustration. The general lack of mobility and slow reaction time of the elderly make it mandatory that hygiene spaces be inherently safe from sharp edges and slippery floor surfaces and that they do not require excessive bending, leaning, or twisting to carry out necessary activities.

Accessibility In addition to more frequent than normal use during the day, frequent use of the bathroom at night is common. Therefore, consideration should be given to direct accessibility between the bedroom and the bathroom. Hopefully, this accessibility would not require passage through an intervening circulation space. If it does, the route shall be direct, unobstructed, and of sufficient width for a wheelchair to pass easily. Indirect accessibility should also exist between the bathroom and the more general living areas of the unit for use of the bathroom by guests.

Visual/audio contact between the bathroom and other areas should be minimized. It should not be possible to see into the bathroom from the living, dining, or food preparation areas. (See Fig. 20.)

Orientation Views to the outside and natural light are not necessary to bathroom functions. Where windows are used, the following criteria pertain:

The designer should make sure that no loss of privacy occurs.

Windows should not be located over bathtubs.

Furnishability and Equipment All personal hygiene spaces shall have the following equipment:

- Lavatory basin (preferred in a vanity counter top)
- Water closet
- Bath or shower
- Appropriate grab bars
- Storage space and mirror
- Toilet-paper holder
- Towel bars

It is essential for the successful functioning of the bathroom or lavatory that certain minimum clear working areas be provided around fixtures. (See Fig. 21.) These requirements are:

Fig. 21 Minimum clearances—personal hygiene.

- **Lavatory Basins:** 3'-6" x 3'-6"; the sink shall be centered on one dimension and at the extreme of the other.

- **Water Closet:** 2'-6" x 4'-4"; the water closet shall be centered on the 2'-6" dimension and located at the extreme of the 4'-4" dimension.

- **Tub and/or Shower:** 2'-4" clear dimension extending out from access point of fixture and at least 2'-8" along its length; the length dimension shall begin from the central end of the fixture.

An emergency call system shall be included in all developments. An alarm button should be placed in the bathroom in a convenient place, but not where it can be set off accidentally.

All bathrooms and lavatories, whether naturally ventilated or not, shall have air exhaust fans venting to the outside and sized according to the code for an interior bathroom.

Spatial Characteristics All personal hygiene spaces, both bathrooms and lavatories, shall have privacy locks which can be easily unlocked from the outside in case of emergency. The key type of emergency release is not desirable because there may not be sufficient time to locate the key in an emergency. Outward opening doors should be used so that people can get in easily to help someone who is lying on the bathroom floor, perhaps unconscious or helpless.

Non-slip, easily maintained floor surfaces which are free from changes in level shall be provided.

The vertical surfaces of bathrooms should be free from sharp corners and edges, unnecessary projections, and breakable materials. This requirement has particular bearing on room layout and the location of bathroom accessories, such as towel bars, paper holders, etc.

Many bathroom layouts are possible but two are the most common, offering solutions to a wide range of concerns. Each has its own advantages. These layouts (Fig. 22) are described for illustrative purposes below.

Layout 1: In the first layout, the toilet is placed by the wall with the lavatory next to the bathtub. This arrangement allows easy placement of the toilet-paper holder and grab bar on the wall while, at the same time, the edge of the lavatory can be used as a support for getting into and out from the bathtub.

A vertical grab bar mounted on the wall near the bathtub in addition to grab bars on the bathtub wall is recommended. An angled grab bar should also be provided on the wall by the toilet.

Layout 2: In the second layout the bathtub is placed against the wall opposite the lavatory and toilet. As in layout 1, separate grab bars should be provided for the toilet and tub. In

this layout the lavatory can be installed in a vanity counter top with sides. The vanity arrangement can support a toilet-paper holder next to the toilet, a towel rack, and perhaps a small grab bar.

Fig. 22 Illustrative hygiene space layouts—all doors 2'-8".

PRIVATE OUTDOOR

Many older people, either by choice or by limitations of their physical conditions, are largely confined to their dwelling units, and access to a private outdoor space over which they have control is very desirable. It offers a welcome change of atmosphere, a chance to grow flowers, cook out, and enjoy the sun. In the event of fire, a balcony can provide refuge and access to fresh air. Provision for private outdoor activities may take the form of balconies or patios. Requirements for patios are discussed in the *Townhouse Development Process*.*

Accessibility The private outdoor space should be directly accessible to the main general living area of the dwelling unit. If possible this area should also be directly accessible to the food preparation area; however, if this is not possible, the indirect accessibility between the outdoor space and the food preparation area should be via a non-circuitous circulation path. Accessibility to all other areas should be indirect and placed as dictated by the functional organization of the dwelling unit, except that there may also be direct accessibility to the sleeping/dressing area.

To protect the privacy of each private outdoor area on the ground floor, direct access from it to the public outdoor area should be avoided by creating an identity for the outdoor private areas. There should be no direct accessibility between the private outdoor areas of separate dwelling units. (See Fig. 23.)

* Michigan State Housing Development Authority, *Townhouse Development Process*, 1970.

Fig. 20 Accessibility of bathroom.

HOUSING FOR THE ELDERLY

Fig. 23 Privacy at ground level.

Visual accessibility between the private outdoor area and interesting views on and off the site should be maximized, while at the same time loss of privacy from views outside the outdoor area should be minimized. The visual accessibility between the general living area of the unit and the general outdoor area should not be impaired by the design of the private outdoor area.

Orientation The configuration and orientation of the outdoor space should be such that sun falls on the space for at least 30 percent of each day during the prime spring, summer, and fall months.

Furnishability and Spatial Characteristics On-grade patios and/or private areas shall be well defined. Location and design shall provide spatial privacy from other living units and from adjacent walks or drives in public space.

Overhead protection of balconies is very desirable but not required. A shelf for plant pots should be included for all balconies at a height of 24 to 30 inches above the floor.

Access doors to balconies should be fully draft-proof and should not be the only source of natural ventilation to the room. The door sill should be kept as low as possible. Passage doors of the swing type are preferable to sliding glass doors and shall be required when economically feasible to eliminate large sills.

Balconies or terraces above the twelfth floor are generally undesirable and should not be provided except in special or unique circumstances.

Where private balconies are not provided for all the dwelling units on a floor, a common balcony shall be provided at a central location.

All balconies, terraces, and patios shall be provided with artificial lighting which is switched on within the dwelling unit. At least one duplex electric receptacle which is weatherproof shall be provided in each private outdoor space.

The criteria for minimum privacy require that screening walls at the sides of outdoor spaces be provided to protect the space from being overlooked by adjoining dwelling units and their private outdoor spaces. The side of the space opposite the building wall may be partially closed and/or defined by planting.

On-grade private space shall have a least dimension of 12 feet and include a paved patio of at least 100 square feet. The remaining area shall be lawn or planting beds.

Private on-grade outdoor spaces may become a security problem if their design provides the

potential intruder with a space completely free from observance and control. Therefore, completely enclosed patios shall themselves be secure. Partially enclosed patios shall be designed so that they can be controlled visually from public areas.

The paved surface in outdoor spaces shall be smooth and free from unexpected changes in level. All steps required to provide a transition from unit floor level to ground level shall have handrails.

Private outdoor spaces above grade (raised terraces and balconies) should be included in the integral design at the beginning of the design process and not added later as an afterthought. Only in this way can the problems traditionally associated with balconies be overcome. Balconies shall have a least clear dimension of no less than 5 feet and a total clear area of no less than 50 square feet for one-bedroom units and 60 square feet for two-bedroom units. Because the elderly are particularly concerned about security and heights, balconies must not only be safe, but they must also feel safe. The use of solid balustrades is desirable. Where this is not possible, a sturdy railing with a large solid top rail

Fig. 24 Example of balcony.

should be used. In either case care should be taken to avoid obscuring views out from the interior of the dwelling unit. For this purpose a solid balustrade to a height of 24 inches with an open handrail above is a good solution. Railings or balustrades shall have a minimum height above the balcony surface of 36 inches and shall extend completely along all open sides of the balcony. (See Fig. 24.)

Whenever possible balconies should be recessed behind the main face of the building because this technique provides a strong sense of enclosure, privacy, and security. Where this is not possible, and where there are adjoining balconies or the balcony is exposed to broad public view, balconies should be provided with screening walls or devices at their sides which achieve privacy and security.

FOOD PREPARATION EQUIPMENT

This section deals with equipment and facilities in the food preparation area of the dwelling unit in terms of quantities, sizes, and detailed location. The question of the functional organization of

the food preparation area and its relationship to other areas of the dwelling unit is discussed earlier. The discussion here is divided into two parts. The first deals directly with the minimum standards against which all proposed developments will be measured and to which all must comply. The second begins with the minimum standards as a base and develops optimum standards for the various components of the food preparation area where appropriate. These optimum standards are not mandatory, and the achievement of some may not be economically feasible within the context of low- and moderate-income housing programs; however, developments which approach or meet some or all of these standards may be given financing priority over those which only satisfy the minimum standards.

Minimum Standards

Refrigerator The refrigerator shall be an upright freestanding model with integral freezing compartment. The minimum acceptable sizes are 10 cubic feet for a one-bedroom unit and 12 cubic feet for a two-bedroom unit. The freezer compartment shall be located at the top or the side of the refrigerator. Refrigerators of the undercounter type are unacceptable because of the excessive stooping required in their use.

The refrigerator shall be of the self-defrosting type. (This is a designated amenity.)

The general storage shelves of the refrigerator should pull out on roller guides and should be removable for ease in cleaning.

Cooking Unit and Oven The cooking unit and oven should be electric; they should be both approved and listed by the Underwriter Laboratories (UL) in their publication, *Electric Appliance and Utilization Equipment List*. Gas cooking devices are not recommended because the elderly often have a poor sense of smell and are forgetful, thus becoming vulnerable to the hazards of fire and explosion.

Cooking devices shall have pilot lights to visually indicate when they are on. A master cutoff switch should be provided if possible. The controls on cooking devices shall be easily read by sight; touch controls should be located at the front of the device to eliminate the necessity of reaching over hot cooking surfaces.

Where an integral cook top and oven unit (stove) are used, the oven should be located below the cook top. Stoves with ovens that are overhead or at eye level are not acceptable because of the reaching required. (See Fig. 25.) The door on

Fig. 25 Oven over stove not desirable.

HOUSING FOR THE ELDERLY

the oven should be hung on the side and swing out if such units are available. This type of oven door is safer and also allows the oven to be used by someone sitting in a wheelchair.

All cook tops must have a hood and exhaust fan mounted directly above the cooking surface. Ceiling-mounted exhaust fans are unacceptable. The cook top shall have four burners and have a minimum width of 24 inches.

Sink The kitchen sink shall be of stainless steel and mounted on the counter top. The minimum overall dimensions are 24 inches by 21 inches. Where counter top area permits, a sink with a double compartment equal to the capacity of a sink with a single compartment is preferred (Fig. 26).

Fig. 26 Desirable knee space at kitchen sink.

Cabinets, Shelves, Counters, and Closets Each kitchen or kitchenette shall have:

1. Accessible storage space for food and cooking and eating utensils
2. Sufficient space for average kitchen accessories
3. Sufficient storage space for those items of household equipment normally used and for which storage is not provided elsewhere such as brooms, mops, soap, etc.
4. Sufficient work surface area for the preparation and serving of food and the cleanup of cooking and eating utensils

Kitchen storage should be provided in the form of wall and base cabinets as follows:

- Shelving: 40 sq ft
- Drawers: 7 sq ft

Kitchen storage should be designed to satisfy the following requirements (Fig. 27):

1. Usable storage space in or under stoves, or under wall ovens, when provided in the form of shelves or drawers that roll out, may be included in the minimum shelf area.
2. Conventional base cabinets over counter tops shall not be deeper than 12 inches and the highest shelf shall be no more than 66 inches from the floor.
3. No cabinet or shelf space should be located above refrigerators.
4. The minimum clearance between counter tops and wall shelves shall be 24 inches at the sink and 15 inches in other locations.
5. At least 80 percent of all shelving shall be enclosed by cabinetry or a pantry. Cabinet doors shall have rounded edges.

Fig. 27 Kitchen storage and counter space.

No less than 10 square feet of counter top work surface shall be provided in kitchens. Counter tops should be approximately 24 inches deep and no higher than 36 inches above the floor. In calculating the length of the counter top, the length occupied by sinks and cook tops may not be counted. Counter tops should have rounded leading edges. Where possible, supplementary counter top space shall be provided at tabletop height so that a resident can use this space for food preparation and for eating light meals. In apartments designed for the handicapped, half of the required counter space shall be at work-table height.

Storage of household equipment shall be provided by a broom closet at least 3 square feet in floor area. These closets shall have shelves for the storage of cleaning materials and they shall have a clear area of sufficient height to accommodate an upright vacuum cleaner and brooms.

A separate compartment with a door shall be provided in each kitchen for a garbage and trash container.

Garbage Disposal All kitchen sinks shall be equipped with garbage disposals that are fully insulated for sound.

Optimum Standards

The following modifications can be made to optimize kitchen facilities.

Refrigerator A horizontally shaped refrigerator that is hung on the wall and mounted in the range of 34 to 72 inches greatly improves usability by eliminating stooping (Fig. 29).

Cooking Unit and Oven A separate cook top mounted on the counter and an oven mounted

Fig. 28 Kitchen arrangement.

Fig. 29 Wall-hung refrigerator.

on the wall greatly increase flexibility of placement and enhance functional organization and usability. The cook top should be mounted no higher than 34 inches above the floor, while the oven should be mounted at waist level (that is, the bottom of the oven should be 27 inches above the floor).

Sinks Sinks should be mounted 34 inches above the floor.

Cabinets, Shelves, Counters, and Closets Many elderly people tend to develop a stoop and are, consequently, shorter than the average adult. As noted earlier, they also have trouble bending and reaching. Therefore, while maintaining the storage requirement of the minimum standards and increasing the work surface area to 12 square feet, the following changes in location and configuration should be made to optimize storage and work surface facilities.

1. Counter tops should be located 34 inches above the floor. This counter area should be supplemented by some counter area at table height to accommodate light dining and food preparation from a sitting position (4 to 6 square feet). Pull-out counters could provide for this need.
2. Shelves 12 inches or deeper should not be mounted higher than 55 inches above the floor when the shelf is above a counter, or 63 inches above the floor when no counter interferes. Shelves of this depth should not be located lower than 27 inches above the floor.
3. Approximately 50 percent of the kitchen storage space should be provided by pantry cupboards or a closet. Shallow pantry shelves (less than 12 inches) may be mounted as low as 21 inches above the floor (Fig. 28).
4. Storage space under counters should be in the form of deep drawers on roller guides rather than cabinets with shelves.
5. Sliding cabinet doors will be substituted for doors of the swing type in the optimally designed kitchen. Where cabinet doors cannot be avoided on cabinets that are 34 inches or higher above the floor, they should be limited to no more than 15 inches in width.
6. All sharp corners and edges will be rounded off cabinet doors.

HOUSING FOR THE ELDERLY

7. Wall-mounted hanging devices for cooking utensils such as pots, pans, large spoons, etc., should be provided at convenient locations.

PERSONAL HYGIENE EQUIPMENT

The following requirements are the minimum equipment specifications for elderly developments; they are also applicable for adoption for use by the handicapped. Each requirement is accompanied by locational and size parameters.

The Lavatory Basin Each bathroom or lavatory shall have a lavatory basin firmly supported to withstand pulling or leaning loads of up to 300 pounds. Vanity cabinets are not recommended as they require excessive stooping and leaning to be used. Vanity counter tops are desirable. Provision for storage should be made in wall-hung cabinetry where necessary.

Basins should be of the cantilever type, either wall-mounted on chair hangers or mounted in a vanity top. An installation of this kind is more easily used by someone in a wheelchair. The most desirable mounting height for basins will provide a minimum clear dimension below the basin and/or vanity top of 2 feet and 2 inches and place the top of the basin and/or counter 2 feet and 9 inches above the floor. Water taps on basins should be low profile with cross shaped or lever handles. Round knobs should not be used. (See Fig. 30a.)

The Water Closet Each bathroom or lavatory shall have a water closet with a seat height of 17 inches (the elderly have difficulty with seating and standing motions). If users in wheelchairs are anticipated, the seat height should be 20 inches. Where economically feasible, the water closet should be of the wall-hung type for convenience in floor cleaning. (See Fig. 30b.) The toilet-paper holder should be located in front of or directly

at the side of the water closet, in a position where leaning or twisting is not required to use it.

Bath and Shower The question of whether a bathtub or shower is more desirable has been debated at length. It has been fairly well established that showers are both cleaner and safer than bathtubs, and showers seem to better meet the goal of extending the span of independent living for the elderly. Many elderly persons, however, enjoy and need the therapeutic benefits of a sitz bath. The situation could easily be resolved by providing both a shower and a bathtub in separate installations; however, this is not economically feasible. It seems, therefore, that a compromise is required, that is, a specially manufactured tub/shower combination. This compromise is the recommended solution, although showers will be considered where central bathtubs are provided on each occupied floor (one tub for twenty dwelling units).

Bathtubs should have controls that are easily operated from outside of the tub without excessive leaning or stretching and should include an automatic mixing valve with an upper temperature limit of 120 degrees F. Tubs shall have a flat bottom with a non-slip surface. Abrasive tapes and heavy, sharp textures should be avoided. The sides of the bathtub should not be higher than 15 inches and the lengthwise dimension should not be less than 60 inches.

Where showers are provided instead of bathtubs (that is, where centralized bathtubs are available), they shall be of sufficient size to allow the bather to stand or sit outside of the area of the spray while soaping his [her] body. The shower enclosure should be equipped with a folding seat as sitting showers prolong independence for those who either require assistance in standing or who are completely infirm. As mentioned above, the shower head should be variable in height and preferably of the detachable type with a flexible head. The highest shower head position should not exceed 60 inches.

Shower controls should be easily reachable from outside the shower stall and should include both an automatic mixing valve limiting the maximum water temperature at the head to 120 degrees F., and a water temperature testing spout to be used by the bather before entering the shower. The soap dish and grab bar should be conveniently located 51 inches above the floor of the shower. Where technically feasible, the raised entrance curb should be eliminated. If glass

is used in the shower enclosure, it shall be tempered for safety.

Soap dishes and similar attachments should be recessed. Water controls should be placed so that they are not a hazard either in normal usage or when the bather slips.

Bathtubs shall be equipped with shower heads. The shower head should be adjustable in height and, preferably, detachable with a flexible head. There should be several wall positions for the head to fix it at various heights. Bathtubs shall be equipped with a detachable seat which allows the bather to shower sitting down. A grab bar and soap dish, placed at a high level about 51 inches from the bottom of the tub will avoid the necessity to bend down for soap or to use the shower curtain for support when taking a shower. Glass enclosures instead of shower curtains are not advisable as they further restrict getting in and out of the tub.

Grab Bars Grab bars are generally overused and sometimes bear little relationship to the anatomy of the human body. If improperly located, they not only fail to serve the user but they can also become a hazard if someone should slip. Grab bars should be used judiciously and wherever possible located to serve more than one bathroom position. Bars should be approximately 1 inch in diameter, be capable of withstanding a pulling or hanging load of 300 pounds, and be fixed to structure members rather than to wall finishes or materials. There should be at least one grab bar at the water closet and another in the bathtub or shower, located and in the configuration shown in Fig. 31.

Storage and Mirror The preferred provision for storage needs is a large mirror behind the lavatory (not a medicine cabinet/mirror combination) and a separate storage unit, built into a wall, large enough to hold both medicine/toiletries and towels. The storage unit should be located so that reaching across counter tops is not required. If towel storage is located externally in a linen closet, the bathroom shall have a mirror behind the lavatory and a separate medicine cabinet which is convenient to the lavatory but placed so that excessive reaching is not required.

Electric Outlets A convenient duplex outlet shall be located adjacent to the mirror and lavatory approximately 6 inches above the height of the lavatory and positioned so that reaching across the lavatory or counter top is not required.

Fig. 30

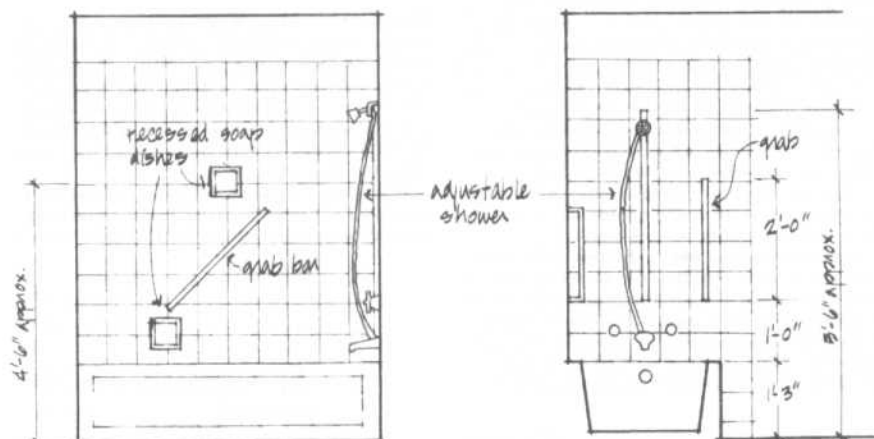

Fig. 31 Bath and shower.

HOUSING FOR THE HANDICAPPED

THE NEIGHBORHOOD

Accessibility to community services and facilities is the first factor to consider in site selection.

Primary services and facilities are: employment opportunities; clinics; vocational rehabilitation programs; inexpensive private and public recreation (such as movies, parks "lively" with activities for participation and view, libraries, etc.); churches; stores including drug, grocery and variety; barber and beauty shops; inexpensive restaurants; schools.

Another important factor is accessibility to public transportation. To the employed impaired citizen, as well as to staff and visitors, good public transportation may be a necessity. To the unemployed, good transportation may keep him in touch with the world, participating in meaningful and dignified activities. Economical public transportation with a nearby stop, without intervening hazards, is highly desirable. Such transportation may be either existing or assured by the time the development is first occupied.

A convenient location is so essential for impaired persons that it may outweigh the other standards and criteria for evaluating residential neighborhoods. Neighborhoods close to specialized services, such as sheltered workshops, should be considered if the neighborhood also possesses the other more generally used services and facilities. It is easier and less expensive to arrange transportation for a particular group of tenants using a single facility than to bring the multiple, less specialized, but equally essential public and private facilities and services within reach of all tenants.

Urban renewal areas, which contemplate commercial shopping centers and other adjuncts to housing needs, may furnish desirable sites.

THE SITE

The criteria for selecting residential sites in general should apply. [These criteria cover economy, topography, subsoil conditions, and existing utility services. Sites subject to industrial smoke, traffic hazards, excessive noise, or polluted air should be avoided.]

The site should allow for development so that structures can be oriented to give residents the advantages of local climate.

Odd or irregularly shaped sites should be carefully evaluated based on amount of usable land and cost of its maintenance.

If the community has restrictive ordinances, zoning, or other local controls which would adversely affect the proposed development in a particularly good location and site, waivers should be investigated. In applying for such waivers, it is important to remember that the housing is to be residential, designed for in-

dependent living. It is neither an institution nor a nursing home.

An important special consideration is slope of the site. For the physically impaired, a comparatively flat site is needed. Steeper and more rugged sites may be used but with doubtful success. Such sites should be evaluated in terms of the costs of any special improvements required to serve the limitations and needs of the tenants. Examples of such extra costs would be those for constructing retaining walls to create useful flat outdoor sitting and resting areas or constructing gently sloping pedestrian ramps throughout the site. Extra maintenance costs (upkeep of banks, lawn areas, and in some climates snow removal, etc.) may result in increased rents.

It is important to have outlooks, both natural and created, that provide interest or beauty and contribute to pleasant living. Many tenants will undoubtedly spend more time at home than would a comparable group of nonimpaired individuals. Views of such things as wooded areas, hills, night-lights, and distant traffic; of planes, boats, trains and automobiles are desirable, and count as positive factors in site selection.

Consideration should be given to the existing and proposed approaches to the site (street improvement, widening; surface; sidewalks) and public utilities.

ACCESS, RAMPS, PEDESTRIAN WALKS

Access All building entrances to be used by the tenants should be approached by paved walks, with nonskid surface, sloped for drainage, but not over 1 in 20 (or 5 percent). Steps should not be used.

Landing platforms at all building entrance doors should be level, sloped only as required for drainage. The platform width should be at least 1 ft beyond the door jams. Platforms should be at least 3 ft deep if doors swing in, and 5 ft deep if doors swing out, but never less than 3 ft beyond the edge of the fully open door. (See Fig. 1.)

Ramps Most wheelchair users can negotiate a ramp sloped 5 percent or less without assistance. Steeper ramps limit independent chair use and should never be used. They are hazardous not only to wheelchair users but also to persons with artificial limbs and to the elderly. Ramp surfaces should be fireproof and nonslip. (See Fig. 2.)

If the vertical height requires two ramps to achieve the properly graded slope, the ramps should be no longer than 20 ft, separated by a

level platform at least 5 ft-6 in. long, to provide ample rest space. Such two-run ramps may be in a straight line; however, a more desirable and safer arrangement would be a 90 or 180° turn at the platform.

When more than two ramp lengths are required, the descent should be broken by turns to be negotiated on level platforms.

The recommended width for a one-way ramp is 3 ft between handrails. At least 6 ft should be provided for two-way circulation.

Handrails and anchors should support 250 lb for 5 min; they should extend at least 12 in. (24 in. is preferable) beyond the beginning and end of the ramp to assist persons with poor vision, and they should be returned to a wall or an upright post for safety.

Handrails installed specifically for children should be at a height of 24 in. Local codes or special safety objectives might necessitate the installation of additional, higher rails.

Fig. 2 Street-curb ramp for wheelchair.

Pedestrian Walks Pedestrian walks at street curbs should be ramped. The ramp should not protrude onto the street but be indented into the curb; it should have a nonslip surface colored orange, or curb jams should be colored to assist those with poor vision. Greater slopes than 2 in 12 could hinder wheelchair use.

PARKING

The parking areas should be moderate sized and conveniently located to provide easy and safe access to entrances. (See Fig. 3.)

There should be no steps or curbs from the parking area to the dwelling buildings or to community space. Space should be planned to eliminate pedestrian circulation behind parked vehicles—a particularly hazardous area for the individual with limited mobility.

A desirable plan for multiple parking space would extend the parking surface into the sidewalk, eliminating the need for curbs. Surface drainage would place the sidewalk at the high point and the center of the parking driveway at the low point.

A pipe rail is necessary between the side-

Fig. 1 Single-run entrance ramp.

HOUSING FOR THE HANDICAPPED

Fig. 3 Parking. Wheel bumper not recommended as car overhangs vary.

walk and parked cars to protect people, particularly those with poor eyesight, from accidents caused by colliding with car bumpers.

For wheelchair users, the minimum width of parking bays is 11 ft (12 ft is desirable). Other orthopedic equipment users will require at least a 9 ft width. The wider bays should be nearest the building entrances. For these tenants, covered parking is desirable.

Parking bays for the nonimpaired may have a minimum width of 8 ft-6 in. under unusual, restricted circumstances. However, the general rule should be 9 ft. Parking areas should not be permitted to obstruct or dominate views from indoor recreation areas or dwellings.

OUTDOOR AREAS, LIGHTING, AND PLANTING

Outdoor facilities and areas (walks, ramps, drives, parking and recreational areas, etc.) should be sloped for drainage and be properly illuminated for safe circulation. Lights should be placed and angled to permit good perception from inside the building.

Existing trees, streams, or rock outcropping of the site should be retained where possible in order to preserve natural beauty. Planting (a few large specimens skillfully located), with emphasis on recreational and sitting areas, contributes to enjoyment and creates a more pleasant environment. Planting around parking area will enhance the site.

The surfaces of concentrated use areas should be paved for maximum safety, use, and interest. For large paved areas, several materials of varied color, design, and texture are recommended to provide a pleasant visual diversity. Nonslip surfaces are desirable—rough surfaces generally present in fieldstone are not recommended.

Rest or sitting areas should be protected from winter winds and excessive summer sun. Some of them should provide a view of the street or of other places where there is animated activity. The best way to provide shade is to use large trees or small, attractive shelters, or both.

Flowering trees and shrubbery can enhance pleasantness and potential enjoyment of the setting.

One-story dwelling buildings and other structures, where appropriate, should have outdoor flower planting areas for the tenants, preferably at or near entrance door.

Every effort should be made to have a sheltered bus stop located at the development. A mail depository box at the same location would be desirable.

Amenities such as a water fountain or a reflecting pool can be included if funds are available. Also, it may be possible to encourage donations of sculpture and other works of art from civic-minded local groups interested in making this housing a visual asset to the residents and the entire community.

Future ease of grounds' maintenance should be kept in mind during the planning and design stage. However, achieving the best possible living environment is the primary objective.

DWELLING STRUCTURES

Entrances

Entrance doors to multifamily structures, community centers, and other public-use space should provide a clear minimum width passage of 3 ft. Entrance doors to individual dwellings should provide a clear minimum width passage of 2 ft-10 in. Thresholds that project above the floor should be avoided when possible. If a projection is unavoidable, it should be no higher than $\frac{1}{2}$ in., feathered to the floor, and 5 to 6 in. wide.

Hinged entrance doors to dwellings are the most economical and safest. Revolving doors should *never* be installed; they must be collapsed for wheelchair users and are particularly hazardous for users of other orthopedic equipment. For entrance doors to a multifamily building, it is best to have automatic door openers, with floor mat activation, flush with floor. Such mechanisms should fully open the door without restricting the clear 3-ft minimum passage. If the opening mechanism fails to function, the door operation should automatically revert to manual operation. Maintenance

of the automatic door opener can usually be reduced by flanking the automatic doors with hinged doors for use of the physically unimpaired. Safety glass vision panels are recommended for solid panel building entrance doors. (See Fig. 4.)

For those who have poor vision or are blind, the floor directly inside or outside the entrance doors to multifamily buildings should either be slightly ramped or have a finish of a different color, distinguishable from the surrounding floor and of a different texture that will provide more grip for shoe soles, thus suggesting caution. Recessed floor mats meet these requirements.

Exterior doors should be covered by a canopy or hood of ample width. A porte-cochere may be feasible. A canopy or roofed-over service entrance also should be provided for ambulances if the development is for elderly and impaired persons. Other entrances may be made from parking areas and grounds. If a clinic is included, a separate entrance should be provided so that persons outside the project who come to the clinic will not use the main entrance lobby.

The operating hardware of entrance doors should be 2 ft-10 in. to 3 ft above the floor. Door checks or closers should be the adjustable tension type, set for minimum pull to assist persons using wheelchairs and other orthopedic devices. Pull handles, push bars, and panic hardware bars with curved ends are best because they contain no hooks or sharp angles to catch clothing. A lever handle which curves close to the door surface is a most suitable operator for latch or lock. Kickplates 12 in. high help to reduce door maintenance by preventing abrasions caused by footrests and axle hubs on wheelchairs, etc. In multifamily buildings, entrance doors normally used by tenants should be provided with key locks which could be set to operate as latches (no keys needed) for daytime use and as key locks at night. A tenant's key would operate these locks and his apartment door lock. Master keys should be provided for management use.

Public Corridors, Galleries

In mild climates, galleries might be appropriate and desirable for cross ventilation, tenant circulation, relaxation, visiting, etc. Galleries should be at least 7 ft wide to allow enough room both for tenant sitting space and two-way traffic of persons using crutches or wheelchairs. Handrails of a bright color or material in bold contrast to the walls should be provided on corridor walls. Such handrails are especially helpful to people with poor vision and to blind persons.

To avoid hazards, doors should not swing into public corridors. Doors to public corridors

Fig. 4 Building entrance doors and doors to public space should have vision panels.

HOUSING FOR THE HANDICAPPED

Fig. 5 Interior stair.

should be identified by raised, brightly colored letters to aid the blind and those with poor vision. An important safety precaution is identification of doors not intended for normal use which would expose blind persons to danger if used. Such doors, when key locked, may provide sufficient protection.

No columns, radiators, drinking fountains, telephone booths, pipes, or other projections should protrude into public corridors.

Public Stairs or Fire Towers

There should be no stairs or steps in the structure except those contained within fire towers for emergency use. Even such stairs should be especially planned. Single-run stairs between floors are not desirable; at least one landing should be used, two in floor-to-floor height over 9 ft. Straight runs between floors are not advisable; runs with 90 or 180° turns at landings are recommended. The most desirable stair would have a 6- to 6½-in. riser and an 11-in. minimum tread. The 11-in. tread places the ball of the descender's foot inside the stair nosing. A safety nosing should be used which does not project beyond the riser and which is distinct in color from the rest of the tread, preferably lighter. Risers should slope forward between 1 and 1½ in. to permit the ascender's heel to rest safely on the tread. (See Fig. 5.)

Stair wall handrails should continue around the platform to help anyone using the stair who is blind or has poor vision. The rails should carry a 6-in.-in. marking for hand feel 2 ft before the first down riser at both floor and landing levels. Steel pipes can be marked by deforming, or by a continuous raised welding, ground smooth, or by a smooth welded strip. Wooden rails can be shaved, notched, or marked with domed-end wood dowels.

Open or grating-type fire escapes are not recommended.

Elevators

It should not be necessary to go through the lobby to reach an ambulance. If there is no

lower-level entrance, the approach should be through a rear or side door in the elevator, thence to the service entrance to the ambulance.

Self-service elevators should level automatically at landings and have automatic sliding cab and hoistway doors with delayed closing, plus two push buttons both overriding the delay timing, one holding doors open, the other to close the doors. An emergency sound alarm system and a cab telephone for emergency use should be installed in each elevator. Cab handrails are required. Cab control panel should be set at a height convenient to persons in wheelchairs, the lowest buttons 3 ft above the floor. The panel location should be on the side cab wall 1 ft back from the front, otherwise a wheelchair will block most of the cab entry.

Back-lighted buttons with raised figures should be used to assist those with poor vision and the blind. These people will need some sounding device which would identify the next floor stop.

Since stairways are of no use to some, consideration should be given to emergency power to operate at least one elevator.

Incinerator Chutes

Incinerator chute hopper doors should be lower than normal. A 2-ft maximum height from floor to hinge is recommended.

Large hopper doors are desirable for convenience and maintenance. For the convenience of persons in wheelchairs, hopper doors should be installed in open corridor or alcove, a location found satisfactory for the elderly. Where codes prohibit this, a waiver should be requested. Anterooms are most inconvenient for many impaired persons—self-closing doors add complications for users of orthopedic equipment and wheelchairs. (See Fig. 6.)

Laundry Facilities

Laundry facilities should be either in one central area or grouped in several areas. Concessionaires who furnish and maintain coin-operated washing and drying machines generally favor, for their convenience, central laundry facilities. Conveniently located group laundries are usually preferred by the impaired and elderly tenants and are recommended.

One automatic washing machine and batch dryer should be installed for each 20 one- and two-person families (one for 17 other families) or fraction thereof. In large central laundries, it is possible to use cabinet-type dryers which can handle more than one batch—useful in projects which include large families. In multifamily buildings, group laundries may be located on each floor or on some floors and not others, whichever is required to meet the demand. In cottage-type developments, laundry facilities

should be located on the basis of walking distance, climate, and convenience.

Laundry rooms must accommodate the necessary equipment: work table, ironing board which is adjustable for standing or sitting, hanging rack, table and chairs for rest and sociability.

Tenant General Storage

Central storage is not recommended for dwellings with one- and two-person occupancy—the general storage provided within the dwellings will suffice.

Mailboxes

In cottage-type developments, where mail is delivered to the individual dwelling unit, a mail receptacle must be provided. The best type is the mail slot with a receiving box inside, the top of which is 2 ft–10 in. to 3 ft above the floor. Impaired persons should not be expected to pick up mail from the floor. A mailbox mounted outside is not desirable. Mail slots should not be located in entrance doors where locked screen doors may make them inaccessible to the mailman or the inside box would interfere with door opening at least 90°.

Mailboxes in a multistory structure are usually installed in rows stacked above each other. Sometimes, because of limited wall space, the top rows are beyond the reach of wheelchair users; for them the locks to their boxes should not exceed 4 ft–3 in. above the floor. The local post office should be consulted when planning this feature.

Separate mailboxes for community space staff workers are desirable, especially when the management office, where they would otherwise receive their business mail, is located at some distance from the community space.

DWELLING UNITS

General

The major problems in designing most "rental housing" for the physically impaired are how to provide maximum livability and safety for persons with impairments that vary in nature and degree. These problems are somewhat mitigated when the housing is to be designed to aid a specific type of impaired individual, such as the blind or the cardiac. The recommendations that follow, however, are based on the fact that the units will be occupied by people who have varying types of impairment, such as those with little or no vision who may or may not use a guide dog; those using wheelchairs or crutches; and those whose physical condition requires the conservation of energy though they use no orthopedic devices.

For room divisions of the dwelling plan, either fixed or movable partitions are suitable. Divisions may be achieved by movable wood closets that do not reach the ceiling or by fixed or movable baffle walls, which are particularly suitable in warm climates. A desirable feeling of larger space is created when the ceilings of adjoining rooms visibly flow from one to another.

All bathrooms should be enclosed by floor-to-ceiling partitions.

Kitchens may be baffled or shielded. When the open plan is used, the kitchen should be fan-ventilated. View of kitchen equipment from the living room and entrance to the dwelling through the kitchen should be avoided.

Each unit should have sufficient space to

HOUSING FOR THE HANDICAPPED

assure suitable living, sleeping, cooking, and dining accommodations plus adequate storage and sanitary facilities. The space should be planned to permit placement of furniture and essential equipment for circulation by wheelchair users and those on crutches. (See Figs. 7-10.)

Living Room

In general, dwelling entrance should be by way of the living room. Entrance through the kitchen is not desirable. For families without children, a combined living-dining room arrangement is preferable to a kitchen-dining room combination. A wheelchair requires at least 2 ft-6 in. seating space at the dining table. Dining by a window, the stool of which is no higher than the dining table, is pleasant, and particularly desirable for the elderly or impaired persons.

Food service from the kitchen to the living-dining area should be direct, without turning corners, and the distance should be as short as possible. A partition between the living room and kitchen should be provided. A baffle wall, with posts attached to floor and ceiling, the material between the posts not reaching either the floor or ceiling, makes a quite suitable partition and creates a sense of space. Prefabricated wood closets resting on the floor and not quite reaching the ceiling also make suitable living room-bedroom partitions in dwellings for one and perhaps two persons. In these small dwellings, the resulting open plan makes the space look larger than it is.

Kitchen

The kitchen for the physically impaired requires more considered attention than any other room. Unlike the living room, such a kitchen may require more space than one for the nonimpaired.

A 5-ft minimum width should be provided for wheelchair turns between counters on opposite walls or between counter and opposite wall.

Counter tops should be set 2 ft-10 in. above the floor, a workable height from both wheelchair and standing positions.

Base cabinets should have a recessed toe space 6 in. deep and 8 3/4 in. high to allow the wheelchair homemaker to get close to the counter and to permit maneuverability. A minimum open space 2 ft-4 in. wide should be provided under the sink. Base cabinet storage space involving hinged doors and fixed or adjustable shelves *should not* be used, because many impaired persons cannot bend down enough to use them. Base cabinet storage is most usable when drawers of various depth are provided and revolving units are installed at the reentrant corners. Pull-out vertical units at one or both sides of the work center also are desirable. (See Fig. 11.)

The kitchen sink should be 4 in. deep, single compartment for one- or two-person dwelling and single or double compartment for larger dwellings. The drain should be at the rear of the sink to provide maximum clearance for knees and clearance under the sink for standard wheelchair arms, 29 in. above floor. At this height, the wheelchair homemaker can reach the inside bottom of the sink without undue stress. This height is also suitable for the stand-up user without unnecessary bending. (See Fig. 12.)

When a stainless steel sink is used, undercoating should be applied to prevent condensation, which also acts as insulation. A single-lever-handle water-control mixing faucet should be provided. This type is the easiest to

Fig. 11 Kitchen sink and base cabinet elevation and section.

operate for those with hand infirmities. The swing spout should have a built-in aerator to prevent splash, especially in a shallow sink. The sink waste line should have a close-fitting elbow leading to the trap installed near, and parallel to, the back wall.

Fig. 12 Sink with knee space. Source: "Handbook for Design: Specially Adapted Housing," VA Pamphlet 26-13, Veterans Administration, Washington, D.C., 1978.

Sustained contact with the underside of a sink or trap filled with hot water could burn persons in a sitting position who lack leg or knee sensation. An insulating board under the sink is not a solution, because the hot water at the faucet and in the sink may be between 130 to 140°F, which is a hazard to a person lacking hand sensation. A much safer way is to control all delivered hot water at a maximum of 120°F. Recent tests showed that with 120°F water at the faucet, the water in the undercoated stainless steel sink was 112°F and a safe 95 to 100°F on the sink's undercoating. The maximum hot-water temperature control should be under management supervision only, which may be the control recommended in the bathroom.

One arrangement for the work center would have a knee-hole opening, 2 ft wide minimum (2 ft-4 in. is desirable), flanked with vertical pull-out units about 12 in. wide. The vertical units should extend from under the counter to

toe space, with content accessible from the knee-hole side when the units are pulled out. One flanker unit could be used for hanging utensils from a peg board. (See Figs. 13-21.)

The other, if installed, could be used for supplies and should have adjustable shelves. Space for the storage of additional supplies should be provided on the counter or in wall cabinets directly in front of the work center.

Another work center arrangement would be the right-hand pedestal 16 to 18 in. wide with drawers, no left pedestal; it is desirable to increase the open space to 28 or 30 in. The storage cabinet above the counter may consist of open adjustable shelves.

A lapboard pull-out shelf beneath the counter at the work center should be installed to provide a working surface for mixing and cutting operations. This shelf should be adjustable in height at 2-in. intervals from about 2 ft-2 in. above the floor to the under-counter posi-

Fig. 13 Work center elevation.

Fig. 21 Work center section. Rear track set $\frac{1}{4}$ in. lower will cause shelf to slope. Recommended.

tion. The hardwood shelf should be cored to brace firmly an 8-in. diameter mixing bowl. (See Fig. 22.)

Under-counter or wall-storage space should be provided, if possible, for a small (perhaps 18- by 24-in.) tenant-owned wheel table. Such tables are useful for moving several items at one time from the refrigerator to the work center, to the dining table, etc.

Fig. 22 Pull-out shelf lapboard. A plastic laminated work surface is recommended. The hole is for an 8-in.-diameter stainless steel mixing bowl which should fit snugly when the top rim is about 1 in. above the shelf.

Wall storage cabinets when mounted 12 in. above the counter provide the maximum convenient storage, accessible from a sitting position. The average height (5 ft-4 $\frac{1}{2}$ in.) female's reach from floor to wrist is 6 ft standing; 4 ft-10 in. sitting in wheelchair, side reach; 4 ft-7 in. sitting in wheelchair under kitchen counter to front of wall cabinet. Standard wall cabinets, 14 in. deep and 30 to 34 in. high with three adjustable shelves, are recommended. The upper shelf of such cabinets is reachable by taller, nonimpaired family members. Cabinet doors should be equipped with 3- to 4-in. drawer-type pulls of simple design and magnetic or nylon roller latches, which are the easiest type to operate. At the work counter, 3-in. adjustable shelves should be installed inside of the cabinet doors to provide convenient storage for numerous small items.

A 5 $\frac{1}{2}$ -in.-wide open shelf placed 7 in. below the wall cabinets may be desirable at some location.

Cabinets should never be installed above counter-top burners or ovens. Such placement creates a fire hazard to the person reaching for stored articles because his clothing might ignite or he might accidentally drop the articles into boiling water or hot grease.

A 14-in.-deep, 18- to 24-in.-wide cabinet, resting on the floor and extending to the same height as the top wall cabinets is also very useful as storage space for the wheelchair user and others. A standard 14-in.-deep cabinet with adjustable 9 $\frac{1}{2}$ -in. shelves and shallow inside-of-door adjustable shelves places within reach from a standing or sitting position many cooking utensils, dishes, and packaged food supplies. The door hinges for such a cabinet should be the continuous piano type. The cabinet bottom can be used for storing serving trays, cookie sheets, muffin pans, etc., when the usual dividers are installed slanting either horizontally or vertically, thus increasing the cabinet's depth and usefulness.

The standard range, with oven below and bottom-hinged door, is unsatisfactory and hazardous for the physically impaired person. Counter-top burners should be provided, preferably with front-of-counter controls. Controls mounted back of the burners are not recommended because of the hazardous reach involved, and controls mounted on the counter to the side of the burners may interfere with the transfer of pots from burners to counter. Easy-to-read large control dials, with safety feature to prevent accidental turn-on of burners, should be provided. To assist the blind and those with poor vision, the control dials, in addition to visual markings, should be marked, shaped, or provided with click stops so that the fingers can feel such marks, shapes, or clicks representing the various heat intensities at the burner. Pushbutton control with indicator light for electrical burners is satisfactory. Burners should not be located below or near a window or near a door. A sep-

arate oven, with a left or right side-hinged door depending on counter-top space and front controls, should be installed so that the height of the pull-out oven shelf at the lowest position is at counter-top level. This permits transfer of hot pans from oven to counter conveniently and safely. Ovens with glide-up doors are also satisfactory.

Electrical top burners are considered by some as safer than gas burners because the gas flame can more easily ignite loose, flimsy garments. Electrical top burners and ovens are generally recommended.

The recommended type of refrigerator-freezer is the standard two-compartment, two-door model with freezer compartment on top and self-defrosting for the food compartment only. Pull-out shelves in the food compartment are desirable. Frequent defrosting of the food compartment is a difficult operation for many impaired persons.

The refrigerator location in the kitchen should never be adjacent to heat-producing equipment such as the oven, top burner, or water heater.

As to garbage grinders, the continuous-feed type of grinder is more convenient to use and costs less to maintain than the batch type and is recommended.

Dishwashers are admittedly desirable, especially those with an electric heat booster.

Whenever possible, natural light and ventilation in kitchens should be provided through windows. Artificial light should be distributed to illuminate all dining and cooking areas effectively. Any required mechanical ventilation should be adequate for removing cooking fumes and odors as well as for summer comfort.

Bedroom

All bedrooms should be partition-enclosed. In one- and perhaps two-person dwellings, one wall may be movable wood closets, a baffle wall, or a sliding or folding partition. Sleeping-living room combinations are *not*

Fig. 23 Bathroom floor plan.

HOUSING FOR THE HANDICAPPED

recommended, nor are room layouts which require the bed to be in a corner or the side of the bed to be against a wall.

For two or more persons, at least one bedroom should be planned for twin beds. Bedrooms intended for the impaired will require more floor area than other bedrooms in order to provide for wheelchair circulation. At least 3 ft (preferably 3 ft-4 in.) must be provided for a wheelchair along one side of one bed and in front of clothes closets and furniture.

Bathroom

The bathroom presents more hazards than any other room; therefore, planning for safety is of utmost importance. A bathroom must be larger than standard to permit wheelchair use. The minimal floor area of a carefully planned bathroom is 40 to 45 sq ft. A bathroom that permits a wheelchair to enter but not to turn around is not desirable. For maneuverability, an area 45 to 55 sq ft. is recommended; however, careful planning is more important than increased floor area. (See Fig. 23.)

Grab bars capable of supporting 250 lb should be provided at the water closet, shower, and elsewhere in the bathroom. Grab bars should be devoid of sharp corners, with ends returning to the walls. Towel bars should be of grab bar quality and strength for safety because they may accidentally be used as grab bars.

Bathtub or shower? We are not considering a hospital, or a nursing home, but a dwelling for independent living and self care. The occupants may be physically impaired, single or married, young or elderly. The question therefore is: what will provide a bathing facility which can be used by the most people, over the longest period of time, with the least hazard? The answer is a specially designed shower with these features:

- No curb or step, for ease of access, including wheelchair.
- Internal dimensions of at least 3 ft-4 in. by 4 ft-6 in.
- Unglazed tile floor—the same for the bathroom floor—which drains into shower.
- 4-ft-6-in.-wide opening with sliding non-breakable doors (not hazardous curtains).
- 120°F maximum temperature delivered hot water under management control; this control would also supply the lavatory and kitchen sink—tenant control for lower temperatures.
- Single lever mixing handle set 3 ft-6 in. above floor, located inside shower compartment, but reachable from outside shower.
- Possibly a flexible metal-covered extension spray head with or without holders at different levels, recommended to be detached for use as hand spray.
- A recessed soap dish—convenient from sitting or standing position.
- Grab bars.

The lavatory should be set 2 ft-10 in. above the floor:

- The maximum depth, 4 in.
- Single-lever water control—aerator spout.
- 120°F maximum-temperature hot water under management control—see shower control.
- Drain opening at the rear of the bowl.
- A close elbow drain, run to the trap, set near and parallel to the wall—so as not to interfere with knee room.

A square lavatory can be installed in a counter top with the faucet at the rear (normal position) or the lavatory can be turned so that the faucet is either to the right or left side. A side arrangement facilitates use by a tenant

Fig. 24 Bathroom-shower elevation. A grab bar above the toilet assists person making a frontal approach. Shower regulator with temperature control is recommended.

Fig. 25 Bathroom elevation. The standard sanitary toilet chair with seat 18 in. above floor is an aid to impaired persons who have difficulty using the normal toilet.

110

HOUSING FOR THE HANDICAPPED

with limited reach and can easily be converted for convenience of future tenants when it is initially provided with flexible-tube water supplies and ample length slip-joint tailpiece waste line. (See Fig. 24.)

The mirror over the lavatory should be usable from both standing and sitting positions. If fixed to the wall, the mirror should be tilted forward at the top. Bottom-hinged mirror provided with a friction stay arm is available. This mirror permits the top to tilt forward to any distance up to 6 in. and can be installed on the medicine cabinet door.

The medicine cabinet should be mounted so as to be accessible from standing or sitting position, and its location in the bathroom should be carefully considered. (See Fig. 25.)

The water closet seat of standard height, 15 to 16 in., can be used by ambulant impaired persons. For the semiambulant and others who find this height difficult, a standard manufactured sanitary chair with arm rests and seat 18 in. high is recommended. The advantage of the chair is twofold; it can also be used in the shower, and would not be present when not needed by the occupant. Some wheelchairs are equipped to be used as toilet chairs. Grab rails should be provided at the closet. One manufacturer can supply an integral seat, cover, and grab bars. (Note: Detachable ring seats that clip on the china bowl or seat are unstable and should be avoided.)

Other recommendations are shown in Figs. 26-34.

Storage

Adequate storage space should be provided within the dwelling. Separate units are desirable for hanging coats and for bedroom, linen, and general storage. The storage units may be closets enclosed by partitions or wood cabinets, fixed or movable, to serve as room dividers. Kitchen cabinets are discussed elsewhere.

The cost closet should permit the hanging of clothing from both standing and sitting positions. For the standing position, the fixed shelf height at 5 ft-6 in. with the clothes-hanging pole below is standard. For the wheelchair position, 4 ft to 4 ft-6 in. is most convenient. The lower shelf and pole unit should be adjustable from 4 ft to 5 ft-6 in. (See Fig. 35.)

For one-person dwellings, the coat closet shelves and pole should be made adjustable. For larger dwellings, both the standing position height and the adjustable wheelchair height should be provided by dividing the closet with a wood partition. (See Figs. 36 and 37.)

The bedroom clothes closet should be divided by wood partitions into two sections, one with shelves and pole for the standing position height and the other adjustable for the wheelchair user.

The linen closet shelves should be adjustable in height, from the baseboard up. Persons in a sitting position can easily reach low shelves, but low shelves are difficult for those on crutches. The linen closet often stores items other than linen, such as clothes hamper, bathroom supplies, etc. Adjustable shelves provide the needed flexibility.

A storage unit should be provided for storing supplies and cleaning equipment, ironing board, canned goods, etc. The unit need not be in the kitchen, but it should be easily accessible from the kitchen. It may be a standard prefabricated cabinet resting on the floor or a built-in closet.

A general storage area and kitchen storage

space may be combined if located conveniently to the kitchen.

Although the general storage area is not primarily designed for the storage of excess furniture, it should be large enough to store foot lockers, suitcases, vacuum cleaner, large and seldom-used cooking utensils, work clothes and work shoes, and—in large family units, folded baby furniture and unused toys.

Increasing the amount of storage space does not always economically resolve the storage problem. The best use of available space can be made by careful arrangement of varying shelf widths adjustable for height and use of hook strips for hanging such items as brooms, mops, vacuum cleaner hose, etc.

Windows

The following hazards should be avoided when selecting and installing windows: windows that project, outside or inside, beyond the wall line and protrude in the path of persons walking; windows that require climbing or leaning out to clean; windowsills too low to provide adequate safety from falling or high sills which block the view from a sitting or bed position. The recommended windowsill height is 28 to 32 in.; [it can be at floor level if the window opens on a terrace or balcony].

Windows should be easy to operate, lock, and clean. Operating and locking hardware should be located for convenient reach from a sitting or a standing position and be of the type easily grasped by arthritic or otherwise impaired hands.

Window types deserving consideration are:

- The modified double-hung window which, in addition to sliding up and down, permits each sash to pivot and swing inward for cleaning with no interference by insect screens or storm panels when used, or curtains, shades, and venetian blinds.

- The awning type with push bar or rotary gear operator set below the screen (some of these windows require the screen unit to be removed to clean the window, others permit

the swing panels to reverse when fully opened for cleaning the outside glass surface). Cleaning of upper glass may be difficult for some.

- The hopper type, somewhat similar to the awning type except that window units open inward and screen is on the outside. This type window may interfere with draperies and shades and may project inward to the point of being a hazard.

- Horizontal sliding windows. Cleaning of upper glass may be difficult for some.

Aluminum windows coated by the manufacturer for protection during shipping and installation have some advantage over windows requiring maintenance painting.

Window items which increase maintenance costs should be avoided. Dissimilar metals that cause galvanic corrosive action in the presence of moisture should not be used. The best rust prevention for steel is hot-dip galvanizing. To prevent condensation and early

Fig. 36 One-person bedroom closet. Coat closet same but smaller.

Fig. 35 Two-person bedroom closet. Coat closet same but smaller.

Fig. 37 Closets. Source: "Handbook for Design: Specially Adapted Housing," VA Pamphlet 26-13, Veterans Administration, Washington, D.C., 1978.

HOUSING FOR THE HANDICAPPED

deterioration, a thermal break is advisable between metal windows (steel or aluminum) and butting interior materials, such as plaster or metal jamb liners. Windowsills are subject to hard usage from flower pots and other heavy objects. Glass glazing compounds which harden make glass replacement expensive; vinyl or snap-in beads are recommended.

Two curtain rods or tracks, as well as venetian blinds or shades, should be provided for windows. Ring pull trim on pull-down blinds or shades is convenient for many impaired persons who use a device with a hooked end for many things. Venetian blinds are practical, though difficult to clean. The general tendency toward excessive glass areas makes the cost to the tenant of providing suitable glare-controlling and cold-retarding draperies unreasonably high.

Doors and Hallways

The entrance door to the dwelling should be at least 2 ft-10 in. wide if door opens 180°, otherwise 3 ft. There should be no entrance step or riser. Any threshold should be at least 5 in. wide, feathered to floor and projecting no more than 1/2 in. above the floor.

Letters or numbers identifying the dwelling should be visible day and night. Raised numbers are more easily seen by those with poor vision and can be felt by the blind. It is also helpful to have color variation on doors or elsewhere near the entrance. Entrance doors leading directly from the outside should have a protective hood or canopy.

The proper width of pass-through doors within the dwelling depends upon wheelchair dimensions and the ability of the individual to operate the chair. Overall dimensions for the standard wheelchair are 24 to 26 in. wide, 42 in. long and 36 in. high. Special-purpose wheelchairs are larger and require more maneuvering space. The pass-through dimensions that follow, which are identified as minimal, represent what the standard American wheelchair is capable of negotiating; the recommended dimensions represent what most wheelchair users can negotiate:

- Hallways in the dwelling: To permit 180° turn, 4-ft minimum width, 4 ft-6 in. recommended.
- Pass-through door—straight-line travel: 2-ft-8-in. minimum if door opens 180°; otherwise, 2 ft-10 in. recommended.
- Pass-through door—90° wheelchair turn from hallway: 2-ft-10-in. door and 3-ft-4-in. hallway recommended; or 3-ft door and 3-ft hallway recommended. (See Fig. 38.)

Closet doors and other non-pass-through doors, 2-ft-6-in. minimum width—horizontal sliding or folding doors are easiest to operate from a sitting position, and they eliminate the danger, especially to the blind, of walking into the edge of a partially open door.

Hinged bathroom doors should swing outward, to remove collapsed person. If the latch includes a lock feature, it should be the type that can be released from the outside. Sliding or folding doors are satisfactory. Two-way swinging doors are hazardous and should not be used.

Operating hardware on doors should be 2 ft-10 in. to 3 ft above floor for all doors in the dwelling, including entrance door. Round or oval doorknobs are the most difficult for impaired hands to operate. Lever handles with ends looped back to the door surface to prevent catching of clothing, etc., are best for operating a latch or lock. Pull handles should be of simple design with no hooks to catch clothing and with both ends returned to the

Fig. 38 (a) Side view of standard adult wheelchair. (b) Plan view of standard adult wheelchair. Source: "An Illustrated Handbook of the Handicapped Section of the North Carolina Building Code," Raleigh, 1977.

door. A 5-in. or more door pull handle, mounted on the hinge side, is convenient for pulling the door shut from a wheelchair.

Kickplates on the entrance door are desirable to reduce damage and door maintenance caused by wheelchair foot rests and wheel hubs. (See Fig. 39.)

Thresholds should not be installed at interior doors or openings.

Floors

For the physically impaired, floor surface materials should have nonslip properties. Some materials are satisfactory when dry but dangerous when wet and therefore should not be used in the bathroom, kitchen, or near the entrance doors when these doors are in the exterior walls. Slippery floor surfaces are particularly dangerous to users of canes or crutches when

Fig. 39 Dwelling entrance opening out. Door pull assists a wheelchair user to pull door shut on entering. The door pull should be on the outside for an inward opening door.

the rubber ferrules become wet or the floor is wet.

Bare concrete floors are not recommended. Carpeted floors, for low-rent housing, cost more initially and in the long run than other suitable floor materials. Carpets need underpads to extend their life and, due to the effort needed to propel a wheelchair, are not desirable for wheelchair users who have arm or hand impediments. Floor materials which require special maintenance equipment or treatment should not be installed inside the dwelling. Floor materials of intermediate colors with a patterned surface should be selected. Very dark or light surfaces, especially solid-colored, show dirt more readily.

For the bathroom and shower, unglazed ceramic floors are recommended. The smaller-sized tiles (2 in. or less) provide some friction at the joints and therefore greater safety. For similar reason, square-edge tiles are more suitable than those with a cushion edge. Coved base makes for easier floor cleaning.

Kitchen floor materials should be grease-resistant. The best materials are those which can be kept clean with warm water and detergent, such as vinyl asbestos.

Floor materials for other dwelling space may be asphalt tile (in the midrange colors), vinyl asbestos, or hardwood. There are numerous wood floor finishes that require little maintenance, such as those formulated with polyurethane (an excellent finish) or epoxy.

Lighting, Telephone, Television, Emergency Signal System

Lighting All light fixtures should be controlled by wall switches. The switches should be uniformly located 2 ft-10 in. to 3 ft above the floor and not over 8 in. from door jamb at latch side of door. A receptacle (not switch controlled) should be combined at some locations with switches, for convenient use of a vacuum cleaner. Tap-type or rocker switches are best for persons with hand impairment. Light fixtures located at a height permitting the tenants to replace light bulbs without using a stepladder are desirable. One way to eliminate this hazard is by the use of a floor or table lamp for room lighting. For this purpose, one receptacle of a wall duplex outlet, conveniently located, should be switch controlled at the room entrance. (See Figs. 40 and 41.)

Adequate light should be provided outside entrance doors so that residents can easily locate their door locks at night. Higher than normal lighting intensity is needed by most elderly and some impaired persons, especially in the kitchen and bathroom.

Wall receptacles should be uniformly placed 18 to 24 in. above the floor to reduce the physical effort of bending. Only those wall receptacles placed above kitchen counters and in dining areas should be mounted higher. Twin wall receptacles are inexpensive and are less hazardous than the cheap substitutes often purchased by tenants.

For safety, the switch(es) controlling electrical outlets in the bathroom should be located outside the bathroom door unless the return wire and the outlet box are grounded.

In low-rent housing, electrical outlets for tenant-owned wall or window air-cooling equipment are permitted subject to approval by HUD-HAA.

The dwelling circuit panel should be located at a height convenient for the wheelchair users. The circuit panel must be of the "dead front" type. Circuit breakers are preferred to plug fuses.

HOUSING FOR THE HANDICAPPED

Telephone In a one-person dwelling, provision should be made for a telephone outlet near the head of the bed; and in all other dwellings, between the beds of the first bedroom. A second telephone outlet could be placed in the living room of dwellings with one or more bedrooms. Some telephone companies will install one plug-in instrument in a dwelling with more than one plug-in outlet. Most low-income tenants cannot afford the monthly expense of two instruments. (See Fig. 42.)

In developments assisted by HUD-HAA, a

Fig. 40 Wall switches.*

Fig. 41 Electrical outlets.

Fig. 42 Telephones.

Figures 40-42 from "Handbook for Design: Specially Adapted Housing," VA Pamphlet 26-13, Veterans Administration, Washington, D.C., 1978.

central telephone switchboard is not recommended because of the manpower operating cost and its resultant effect on rents.

A house emergency telephone and/or other signal device should be installed in each elevator cab. The answering service should be in the management office and the custodial apartment, or other 24-hr service if found to be economical.

Television A television antenna system should be provided when needed for good reception.

Emergency Signal System The system would include one large-diameter pushbutton in the bathroom, another near the head of the bed in a one-person dwelling, and one between the beds of the first bedroom in all other dwellings. Both pushbuttons activate an audio and visual unit located outside the dwelling. A third unit, which can be activated simultaneously, should change the dwelling entrance door from locked to unlocked. The activated unit should be on continuous duty, allowing it to remain in operation until reset. The audio unit tone should be distinct and should differ from the fire alarm. A secondary power supply should be considered for the emergency signal system and the fire alarm.

The audio and visual units may be located outside the entrance door, inside an adjacent dwelling, or in a central location.

Heating

The heating system should be designed to maintain room temperature of 75°F for the physically impaired or elderly.

Exposed vertical heating risers and exposed radiators are dangerous. Such equipment can cause severe burns to persons who, in portions of their bodies, have little sensation to heat. All vertical heating pipes should be concealed and radiators covered with cabinets.

In bathrooms, the use of a ceiling-type heat lamp, thermostatically controlled and operated by a manual wall switch, is recommended as safe and economical, providing instant heat day or night. Exposed heaters, radiators, or heat riser pipes are not safe and should not be used.

In multistory structures, a central heating plant is generally most economical. For one-story structures, a central heating plant is costly due to the installation of distribution mains. Either forced warm air or forced hot water as individual units or group plants could be used for one-story structures. The final determination should be based on a detailed utility analysis.

Excessive window glass areas increase heat loss and therefore fuel cost. In summer, rooms with a south or west exposure receive the rays of the hot afternoon sun, which raises the temperature in the unit. Large glass areas exposed to summer sun or winter cold require curtains or draperies, an expensive tenant item.

Whatever form of heat is provided, tenant control is recommended, preferably by thermostat or, in the case of radiators, by shut-off valves.

Domestic Hot Water

In warm climates, individual water heaters installed in a closet with outside entrance makes for ease of maintenance and facilitates management control of water temperature setting.

Custodial Dwelling

The need for a custodial dwelling unit should be considered. Such dwelling should be centrally located and have at least two bedrooms,

to suit the housing needs of a couple with children. In a multistory structure, the custodial dwelling should be on the ground floor.

To have the custodian living within the development is desirable and necessary for the physically impaired and the elderly. Therefore, justification for including a custodial dwelling should show the number of tenants who are impaired or elderly.

Although the custodian is an employee with specific work assignments, he should be available for emergencies when off duty. The custodian's wife might be available during the day; however, in most developments there is a management office open during working hours.

COMMUNITY SPACE

General

The following recommendations apply particularly to multiuse community space and to those less specialized community facilities most frequently developed in conjunction with residential housing developments. Local considerations will govern the number and nature of specialized community facilities developed in combination with a residential facility for the physically impaired. Because the range of possibilities in such specialized facilities is so vast—from health clinics to sheltered workshops offering specific types of employment opportunities—anyone undertaking to design them should consult with program directors.

Before the architectural plan and functional layout of the community space can proceed, the local need and available services should be explored in cooperation with local agencies which will finance the staffing and operate the space after it is constructed.

Since the maximum space permitted is determined by the number of families in each development, it is not possible to provide in all developments, especially the smaller ones, space for all activities. The space planning for some areas should provide for functional use of the maximum number of activities. Areas or spaces generally considered desirable are a lounge combined with the entrance lobby; group recreational space with kitchen; craft area; library; clinic; facilities such as toilets, public telephones, drinking fountains, and vending machines especially designed or arranged for orthopedic equipment users; and a separate space for the resident children's activities.

Space to be allotted as a health clinic should be planned as a separate functional unit. Health clinic space rarely can be combined with recreational or other space.

Indoor community space should be closely related to outdoor recreational areas with easy access and no intervening stairs or steps. Indoor space should have natural light and ventilation with pleasant outward views. It is not desirable to locate community space in basements or on rooftops detached from outdoor recreational areas.

In general, floor surfacing suitable for the dwelling area is suitable for indoor community space. It may be advisable, however, to install nonstaining flooring in certain special use areas, and more durable flooring—such as nonslip terrazzo, unglazed tile, or quarry tile—in corridors, entrance lobbies, and other concentrated use areas.

General illumination should be of multiple control to allow for varying degrees of intensity. The maximum should be at about 30

HOUSING FOR THE HANDICAPPED

foot-candles at table height. Supplemental movable lights (floor and table lamps in the lounge and library) should be provided at required utilitarian locations for decorative and functional use. Avoid creating hazards by exposed extension cords to floor and table lamps.

There should be no hazards within the community space, such as thresholds, freestanding columns, pilasters, projecting radiators, or drinking fountains.

Air conditioning of all community space used by physically impaired or elderly should be considered.

Lounge

When combined with the entrance lobby of a community building or the elevator lobby of a multistory structure, a lounge provides increased activity and interest. The elderly and the impaired enjoy watching the going and coming tenants and visitors. In cold climates a vestibule entrance is necessary.

Locating the mail delivery room in the elevator lobby near the lounge is recommended.

The décor of the lounge should be coordinated—wall colors, white ceiling, accent colors—in draperies, furniture, lamps, and plastic or cloth upholstery materials. Woven cloth upholstery material used in the lounge must be stainproof.

Selection of chairs and sofas for the physically impaired, especially the semiambulant, deserves special consideration. Seat height 18 in. above floor is best. Sturdy arm rests help the impaired to rise. Chairs should not overbalance when weight is applied on the arm rest. Deep seats (over 20 in.) are undesirable. Semistiff, upholstered furniture is recommended.

Recreation or Multipurpose Room

This space may be subdivided by sliding or folding soundproof dividers or doors—the ceiling should be acoustically treated. The space should be suited for meetings, movies, concerts, plays, lunches, etc. Because of the nature of such activities, convenient storage space for tables and other items should be provided. An inventory of the items is needed to adequately plan an orderly and functional storage—flexibility of use with adjustable shelves is desirable.

Building codes may require emergency exits, but at least one exit door may be desirable for departing guests after evening affairs.

Structural columns or other obstructions within this space should be avoided or eliminated if possible in order that the space may function as one room for certain occasions.

Tables without aprons, which will permit wheelchair arms to fit underneath, are recommended—they also take less space to store.

Kitchen

A kitchen should be provided adjacent to the recreation room. Equipment and arrangement should facilitate efficient and functional food preparation and clean-up. The kitchen may be used by the tenants.

The kitchen should be planned and designed to be useful in demonstrating and instructing on food preparation, in planning balanced diets, and in conducting various consumer education activities. For this purpose, the division between the recreation room and kitchen should be a sliding or folding divider or doors which can be locked or secured.

A two-door refrigerator freezer with auto-

matic defrosting food compartment is recommended. In large kitchens, consider how best to provide cold drinking water.

A kitchen service entrance should be planned to accommodate delivery of supplies, catering service, and garbage and trash removal. A garbage grinder may be installed in this kitchen—the continuous-feed type is recommended.

Floor and wall surfaces should be of easily cleaned materials and finishes. Wall cabinets should have adjustable shelves. At least one closet, with lock, for storage of staple supplies should be provided, as well as a cabinet for mops, brooms, and cleaning materials.

Craft Activity Area

The space for craft activities should have maximum flexibility for varied arrangement. Fixed partitioning of cubicles is *not* desirable—no flexibility. It is best to concentrate the craft space in one room, dividing the space with movable (on casters with step-on brakes) wood storage cabinets for materials and supplies. This provides for multiple use of space and permits adapting space size to tenant interest and various activities.

The movable divider cabinets should not extend to the ceiling. A height of about 4 ft provides views [to the person who is] standing and improves ventilation and distribution of light; further, no change in the prearranged distribution of air conditioning is required. The cabinet units should be of sizes easy to move. Standardized units are advisable, but they should be selected or designed for the materials and supplies to be stored. It is also advisable to have cabinets that can be locked

and shelves that can be adjusted. Some drawer-type storage space may be desirable. Apronless tables are recommended.

Special consideration should be given to providing outlets for both 110 and 220 volts in craft activity area—consult with operating staff.

Library

The larger community spaces may provide, if need is established, an area for a branch of the city library, which will furnish book stacks. When the book stacks can be locked or otherwise segregated from the rest of the library, then the area generally used for reading could on occasion be used for small gatherings or other uses—again, flexibility. If possible, this space should be large enough for apronless tables and for chairs. Since smaller projects seldom can afford a separate library, the lounge may be provided with adjustable shelves for books and periodicals. This same idea, while less desirable than a separate library, may be considered for large projects.

Health Clinic

A clinic can contribute substantially to the welfare and continued independence of the elderly and physically impaired. Clinic space may be provided when such facilities are not available near the site.

In small developments, the permissible clinic space may consist of an office and examination room for use of doctors and nurses who visit during scheduled periods.

In larger developments, space for a variety

Fig. 43 Toilet stall. (a) Plan. (b) Elevation. (c) Isometric. Source: "An Illustrated Handbook of the Handicapped Section of the North Carolina State Building Code," Raleigh, 1977.

HOUSING FOR THE HANDICAPPED

of health services may be provided, including physical therapy and hydrotherapy, a special need of the physically impaired. Occupational therapy may be conducted in the craft activity area. This type of clinic would generally be active each work day and should have a waiting room with a separate outside entrance permitting nontenant patients to come and go without traversing the lobby or lounge.

Washrooms

Separate washrooms for each sex should be provided in community space. At least one water closet compartment for the semiambulant and wheelchair user should be provided in each washroom in addition to other plumbing fixtures.

Fig. 44 Wall-hung toilet—desirable.

The washrooms should be located to permit convenient use by outside visitors to the clinic and tenants using the various activity areas.

The toilet stall illustrated in Fig. 43 is a possible solution for persons using wheelchairs.

Maximum maneuverability for persons using crutches or wheelchairs is provided in toilet stalls, with the toilet fixture set toward either side wall.

Horizontal grab bars should be installed on the side and rear wall of the water closet compartment. Such bars (1½-in. outside diameter) should be at least 4 in. from the wall to prevent pinioning the wrist, hand, or arm in case of a fall. Grab bars should support 250 lb.

The water closet seat should be 18 in. above the floor. A wall-hung closet is most suitable for the semiambulant person—it also makes for ease of floor cleaning and sanitation. (See Fig. 44.)

Fig. 45 Wall-hung urinal.

Urinals in the men's room should be of the wall-mounted type, also for sanitary reasons. The front lip of the urinal should be 18 to 19 in. above the floor, which is convenient for persons in wheelchairs as well as others. (See Fig. 45.)

The installation of lavatory and wall mirrors is discussed in the section on "Dwelling Units," under "Bathroom."

A separate staff washroom which can be used by both sexes should be provided in the clinic—two washrooms in the large clinic.

Public Telephones, Drinking Fountains, Vending Machines

Public Telephones The standard public telephone booth is not usable for most physically impaired people.

To assist persons with hearing disabilities, telephone receivers should have adjustable amplifiers.

Fig. 46 Semirecessed model with projecting basin is recommended because the wheelchair approach is parallel to the wall. A frontal approach is difficult. Two units may be connected to one water chiller. The second unit should be set 40 to 42 in. above the floor and 5 to 6 ft from the other. The water stream rises about 4 in. above the bubbler orifice.

The pushbutton-dial receiver is more desirable for the impaired than the rotating dial.

The standard coin-box receiver mounted above the table or shelf elevates the coin slot 4 ft above the floor, which is not convenient for some with physical impairments. A desk-type telephone, resting on a table or shelf about 31 in. above the floor, is the most convenient (bottom of shelf must clear wheelchair arm rests). For wheelchair users, the desirable height for coin slots is about 3 ft above the floor or 6 in. above the counter top. The local telephone company should be consulted for advice regarding available special and standard equipment which is especially desirable for the physically impaired.

Drinking Fountains The standard adult drinking fountain is satisfactory to all except wheelchair users. For wheelchair users, the fountain bubbler should be 31 to 33 in. above the floor. Two-level drinking fountains that satisfy both standard and wheelchair height requirements are available, or a low-level unit can be added

on the standard fixture. Persons in wheelchairs can use a children's drinking fountain 31 in. high. Pushbutton control is best for persons with impaired hands. Some drinking fountains are available with both hand and foot control. (See Figs. 46 and 47.)

Drinking fountains with paper cup dispensers should have the dispensing mechanism 30 to 34 in. above the floor. Drinking fountains resting on the floor and projecting into the corridor are a hazard; recessing into wall pockets makes floor cleaning difficult.

Fig. 47 The floor cabinet model is available with an additive basin; while this two-level unit would serve the dual use, it is not recommended because of the hazard created to persons with poor vision and to blind persons who will be using the wall handrail.

Vending Machines The need for and location (not in prominent view) of vending machines which dispense soft drinks, etc. should be considered.

Other Areas

The minimum corridor width should be 6 ft. Grab rails should be provided on each side wall. (See chapter on dwelling structures for special assistance to those with poor vision.) The minimum door width should be 3 ft. Doors from the corridor to the various rooms, when fully open, should not extend into the corridor. They are a hazard, especially to persons with poor vision.

Consideration should be given to the need for a staff management office. In multistory buildings, such an office should be located to provide an unobtrusive view of the lobby entrance and elevators.

Office space in which tenants may, in privacy, discuss problems with counselors and [which may also serve] for other uses should be considered.

Consideration also should be given to temporary coat and umbrella storage facilities for tenants and visitors using the recreation or multipurpose rooms. This facility is best located where it can be visually supervised. Closed cloakrooms should be avoided.

Certain rooms and storage areas will require locked doors.

HOUSING FOR THE HANDICAPPED

CENTRAL DINING

Seating for wheelchair users should be on at least 2'-6" centers. Tables should be 3'-6" wide if chair users are to face each other. Wider tables are not recommended because of chair users' restricted reaching ability. (See Fig. 48.)*

Fig. 48 Clearance for central dining-wheelchair users.

PARKING†

Parking Space Requirements

Parking spaces specifically designed for restricted individuals should be set aside and properly identified through the use of signage so that the

spaces are not used indiscriminately by people not needing them. (Fig. 50).

Special elevated platforms, or mechanical lifts

attached to vehicles must be provided to facilitate boarding and disembarkment by wheelchair bound people from mass transit vehicles.

Fig. 49 Clearance for handicapped parking space.

* Text and Figs. 49-50 from "An Illustrated Handbook of the Handicapped Section of the North Carolina State Building Code," Raleigh, 1977.

† This text and Figs. 51-53 from "Barrier-Free Site Design," The American Society of Landscape Architects Foundation, HUD-PDR-84, Washington, D.C., 1975.

Fig. 50 Suggested signs displaying the international symbol for accessibility.

PARKING FOR THE HANDICAPPED

1. Parking spaces of greater width than normal are necessary for people who are disabled and use mechanical aids such as wheelchairs, crutches, and walkers. For example, persons who are chairbound must have wider aisles in which to set up their wheelchairs.
2. A minimum of two spaces per parking lot should be designed for use by physically restricted people, or at least one space per 20 cars, whichever is greater.
3. These spaces should be placed as close as possible to a major entrance of a building or function, preferably no more than 100'-0" away.

4. Parking patterns are described in 5 and 6 below (Fig. 51).

5. Parallel Parking:

Parallel parking spaces should be placed adjacent to a walk system so that access from the car to the destination is over a hard surface. Such spaces should be made 12'-0" wide, 24'-0" long and should either have a 1:6 ramp up to the walk, or should be separated from it by bollards or some other device if the road level is at the same elevation as the walk. These areas should be designated as special parking since they may otherwise appear to be a drop-off zone.

6. 90 Degree and Angled Parking:

a. Spaces designed for use by disabled people functioning with large mechanical aids as described above, should be 9'-0" wide as a minimum. In addition to the 9'-0", a 3'-6" to 4'-0" wide aisle between cars should be provided for access alongside the vehicle (Figs. 49 and 54). It is important that there be plenty of room to open the car door entirely, and in the case of a dependent chairbound person, that there be room for friends or attendants to assist him [or her] out of the car, into his [or her] chair, and away from the car.

b. The 9'-0" wide standard space width for a parking stall, with no aisle between spaces, does not drastically hinder semiambulant people with minor impairments, but an 8'-0" width, unless used exclusively for attendant parking, is too narrow and should be avoided.

c. A 4'-0" minimum clear aisle width should be provided between rows of cars parked end to end. The overhang of the automobile should be taken into account so that the island strip is wide enough to leave a 4'-0" clear aisle when the stalls are filled. A strip 8'-0" wide is a recommended minimum for an on-grade aisle, and 10'-0" is a recommended minimum where the aisle is raised 6" above the parking level.

d. If the aisle between rows of cars is not at the same grade level as the cars, then ramps must be provided to mount the curbs. A 1:6 (17%) ramp is suitable for such a short distance.

e. Economically, the installation of an on-grade 4'-0" wide pathway is less expensive than a raised walk. Precast car stops to delineate the passage can be used providing that a 4'-0" wide space between the ends of stops is maintained to allow access to the main passageway.

SPATIAL REQUIREMENTS

Building: Approximately 6,650 square feet for a 12-person home and 7,400 square feet for a 16-person home are allotted. This area includes space for the garage and basements. The building can be arranged on one level or on two full or partial levels.

Entry

Major This spatial requirement varies according to the inclusion or exclusion of the vertical circulation element within the space. Normally, an area of approximately 90 square feet should be sufficient. A closet with a minimum of 6 linear feet of hanging space should be adequate.

Minor The size of this space varies; however, it should be adequately sized for ease of circulation through it.

Living Space

This space varies in size. In a typical 16-resident group home it is approximately 400 to 500 square feet.

Recreation Room

This space varies in size. In a typical 16-resident group home it is approximately 400 to 500 square feet and as previously indicated should be sized to seat all residents. It is required that direct access suitable for use by the physically handicapped be provided from the main living area and to the common outdoor activity area.

Kitchen

The area designated for food preparation shall meet all of the requirements of the Michigan Department of Public Health, Michigan Department of Social Services, and the applicable portion of the F.H.A. Minimum Property Standards for Multifamily Housing. The typical kitchen is equipped with the following appliances:

- refrigerator
- freezer
- commercial dishwasher
- cooktop range with exhaust hood
- double oven
- disposal

Dining

The dining space shall have a glazed area of at least 10 percent of the floor area. The following clearances and sizes will be assumed for design purposes:

- 2'0" for table edge for each diner
- 3'0" minimum table width for tables seating four to six persons
- 3'3" for larger tables
- 4'0" minimum clearance between the table edge and obstruction where seating and circulation occurs
- 3'0" for circulation clearance
- 2'6" for seating clearance table to obstruction

Clearances are shown in Fig. 1

Powder Room

This space should be sized to accommodate physically handicapped residents. A water closet and

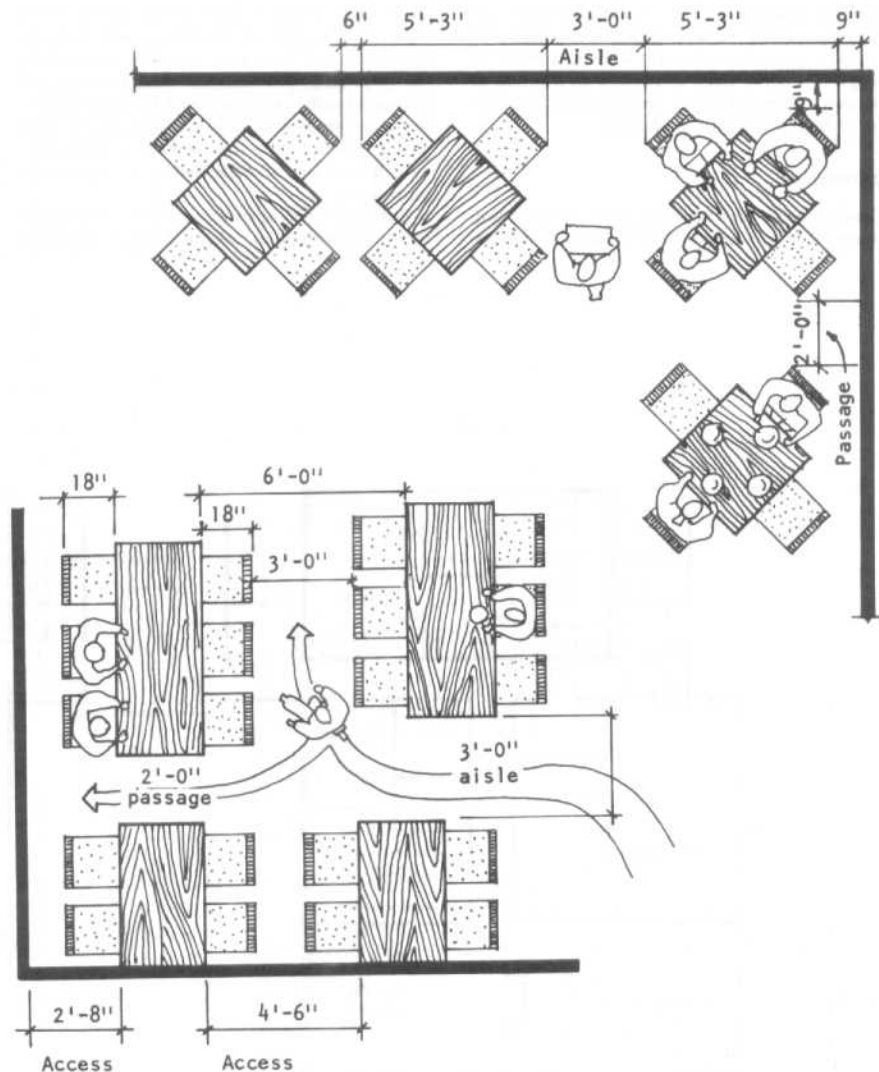

Fig. 1 Clearances for central dining.

a lavatory without vanity base should be provided.

Bedroom

No resident room shall accommodate more than three persons. Each occupant of a room shall be provided with a separate storage closet of at least the following:

- 4'0" x 2'2" clear and an opening width of at least 3' clear.
- The closet shall be equipped with a shelf and hanging rod.
- The bedroom shall be equipped with windows whose glazed area is at least 15 percent of the floor area of the room.
- Windows shall be operable and have a free air ventilation area equal to half the glazed area.
- Resident bedrooms shall accommodate at least the following:

- 2 beds: 3'3" x 6'6" min.
- 2 dressers: 3'0" x 1'6" min.
- 1 lounge chair: 1'10" x 1'10" min.
- 2 bedside tables: 1'0" x 1'0"

- Specially designed desks/storage units may be used.

Minimum clearance shall be maintained as follows:

- 1'6" between wall and the side of bed that is least used
- 3'0" in front of dresser
- 3'6" diameter area for dressing
- 2'6" for access to and use of table as a desk
- 3'0" door opening
- 2'6" general circulation

The bedroom shall be designed to provide a clearly defined area within the room for each occupant. It is preferable if one occupant does not have to violate the area of another in order to get to or from the room entrance or [sic] the bedroom.

If possible, the room should be designed so that there is a visual separation between the sleeping areas. Generally, resident rooms should be grouped together and served from common halls or foyers. These halls shall provide direct access to shared facilities for the residents without the necessity of going out of doors. The room

Residential

GROUP HOMES

specially adapted for the handicapped shall have such access only via level floors or elevators. The acoustic separation of party walls and floors of a given resident room shall have STC rating of 45 and INR rating of +5. The ceiling height shall be at least 7'6" (8'0" preferred).

BATHROOM

One bathroom shall serve every two resident bedrooms, that is, a total of four residents. The bath-

room shall contain a water closet and a vanity base with a pair of lavatories with cabinets mounted on it. The homes specially adapted for the physically handicapped shall have a stall shower of sufficient dimensions to allow soaping out of the spray instead of a tub. Lavatories shall be located in vanity tops without a base. Tubs may be allowed if equipped with appropriate grab bars.

Bathroom shall open directly off the resident's room. All bathrooms will be finished with non-

slip materials and will include a storage space for each individual's personal toiletries.

OFFICE

The office shall contain no less than 100 square feet in area. It shall have walls, floors, and ceilings with a rating of 45 STC and +5 INR to insure privacy during counseling.

GENERAL CONSIDERATIONS AND RECOMMENDATIONS

Need	Design recommendations
1. Location	a. Accessible to public transportation. b. Centrally located—not remote but with element of privacy. Near other public facilities, if possible, e.g., museums, parks, schools.
2. Site	Level ground is desirable.
3. Layout	a. One level is desirable—elevator for more than two floors. b. Window views while seated and physical ease of access to outdoor activities. c. Seats at stair landings.
4. Heating and Ventilation	a. Mechanical heating and ventilation throughout. b. Separate thermostatic control for selected program areas.
5. Utilities	a. Adequate wiring for electric kitchen appliances, kiln, power machines, audio-visual equipment, etc. b. Waist-high electric receptacles in all rooms and convenient outlets as required for power tools, projection equipment, etc. c. No loose floor wiring. d. Intercommunication system for music, announcements, etc. e. Fire alarm.
6. Lighting	a. Intensified but without glare. b. Additional lighting in craft areas for depth perception.
7. Acoustics	a. Sound control and acoustical ceilings throughout—special provisions where required. b. Investigate problems of hearing aids in large areas. Individual head phones where microphone is used.
8. Equipment	a. Recessed water fountains, fire prevention and control equipment, radiators, pipes, etc.
9. Safety	b. No projecting parts. a. All flooring slip-proof. b. Elimination of door sills. c. Draft control. d. Simple circulation between program areas in order to avoid confusion. e. Doors wide enough for wheelchairs. f. Handrails along hallways.
10. Color	a. Color identification throughout, specifically exits, fire equipment, etc. b. Light, bright interior colors. c. Avoidance of institutional character.
11. Storage	a. Storage for each area. (See program design recommendations.)

ARRIVAL AND ENTRY

Need	Means and equipment	Design recommendations
1. Pre-arrival	a. Pickup car or bus	a. Storage for car or bus
2. Arrival and Departure		
Members	a. Foot b. Wheelchair c. Car d. Bus	a. Sheltered approach b. Entry without steps c. Slip-proof pavement d. Car and bus turnabout e. Accommodation for first high riser for bus f. Parking area
Staff, Volunteers, Other Personnel	a. Foot b. Car	a. Parking area: Reserved area b. Separate entry
Visitors	a. Foot b. Car	a. Parking area. Same as for members
Supplies	a. Foot b. Car c. Truck	a. Separate receiving-unloading area b. Separate receiving-unloading entry c. Concealed garbage and refuse storage and pick-up area
3. Entry		
Checking of hats and coats	a. Chair b. Tables c. Counter d. Clothes racks e. Shelves	a. Checkroom with storage space for hats, coats, raingear, parcels b. Counter space for 2 attendants c. Pocketbook ledge d. Good checkroom ventilation

SENIOR CITIZENS' CENTER

Need	Means and equipment	Design recommendations
		e. A few tables and chairs to facilitate removal of boots, rubbers, heavy outer clothing
		f. Sufficient space around checkroom for traffic and for checkroom service waiting line.
		g. Toilets
Thrift & Gift Shop	a. Counters b. Tables c. Chairs d. Display case e. Show window f. File	a. Locate near entry with street or lobby show window.
Reception and Daily Registration Desk	a. Desk b. Two chairs c. Bulletin Board	a. Lobby area for daily registration of members at desk and for registration waiting line b. Well-lighted lobby area for bulletin board

SPACE CONSIDERATIONS

Space	Recommended area/person	Recommended minimum areas
1. Entry/Reception	15 sq. ft./person	150 sq. ft.
Coat-room storage	one-linear foot = 6 garments	50 sq. ft.
2. Quiet Lounge & Library	35 sq. ft./person plus book stack area	
3. Noisy Lounge	35 sq. ft./person	
4. Auditorium and/or Dining	7 sq. ft./person for seated Aud. use 15 sq. ft. for dining and table set-up	
5. Kitchen and Storage	*See footnote	
6. Meeting rooms and/or Classrooms	25 sq. ft./person	
7. Arts and Crafts		
a. Wood working	60 sq. ft./person	600 sq. ft.
b. Painting, ceramics and needlework	25 sq. ft./person	250 sq. ft.
8. Photography Dark Room	80 sq. ft.	80 sq. ft.
9. Arts and Crafts storage	—	80 sq. ft.
10. Administration & Staff Offices		
a. Director and other offices for 1 to 2 persons	—	130 sq. ft.
b. Staff and/or general office	50 sq. ft./person+Files	150 sq. ft.
c. Private Consultation	50 sq. ft./person	600 sq. ft.
d. Staff Rest room	25 sq. ft./person	150 sq. ft.
11. First Aid Room	—	100 sq. ft.
12. Storage (General)	—	100 sq. ft.
13. Toilets	—	(See local or Nat'l Building Code)
14. Outdoor Recreation Areas	Varies with site and climate	
15. Parking	Allow 250 sq. ft./car for parking	

* Note: Size of kitchen would depend on the agency program in respect to serving of meals, snacks, parties, etc.

These rooms may be scheduled for special use. Provision should be made for separate smoking and nonsmoking areas.

LOUNGES AND AUDITORIUM

Need	Means and equipment	Design recommendations
1. Quiet Lounge		
Activities		
Reading	a. Comfortable chairs	a. Self-contained lounge area
Writing	b. Tables, desks	b. Fireplace
Relaxing	c. Books, newspapers,	c. Storage space for:

SENIOR CITIZENS' CENTER

Need	Means and equipment	Design recommendations
Quiet games	magazines	1. Games (Chess, checkers, dominoes, cards)
Meetings	d. Games and cards e. Folding chairs, tables	2. Extra folding chairs & tables 3. Books, magazines, newspapers
2. Noisy Lounge		
Activities		
Cards	a. Chairs and tables	a. Self-contained lounge area
Active games	b. Extra folding chairs and tables	b. Storage space for:

Parties (small)	c. Pool table	2. Folding tables and chairs
Meetings	d. Piano	3. Record player
3. Auditorium		
Activities		
Parties	a. Chairs—folding and nonfolding	a. Area for theater; nonpermanent type seating
Dancing	b. Tables—folding and nonfolding	b. Stage
Movies		c. Easy access to stage
Stage Productions	c. Audio-visual equipment	d. Back-stage dressing room
Concerts	d. Piano	e. Storage for:
Speakers and Panels	e. Other musical instruments	1. Folding chairs and tables
Large meetings	f. Music stands	2. Costumes
Carnivals; bazaars	g. Public address system	3. Decorations
Community Service Projects	h. Decoration	4. Musical instruments
Seated dinners for entire membership	i. Wall exhibits	5. Music stands
		6. Audio-visual equipment (Storage area may be under stage or adjacent to room)
		f. Near kitchen and/or dining room
		g. Near toilets
		h. Wiring for audio-visual equipment must avoid loose floor extension
		i. Wall display space and cabinets
		j. Folding doors

DINING AND REFRESHMENT FACILITIES

Need	Means and equipment	Design recommendations
1. Food Preparation and Service	a. Cooking and baking equipment b. Refrigeration c. Washing equipment for: 1. Dishes, cutlery 2. Pots and pans 3. Kitchen and dining room cleaning d. Cabinets for: 1. Dishes, pots, cutlery 2. In-use food supplies and staples e. Counters for: 1. Food preparation 2. Food Service 3. Return of trays, used dishes f. Garbage disposal equipment g. Coffee urns h. Bulk food supplies	a. Electrical dishwasher, electric stoves, electric refrigerator b. Easy access cabinets—not more than 63 inches high, nor lower than 27 inches for food, dishes, pots, pans, etc. c. Exhaust system d. Counter space for several serving stations e. Counter space for tray returns f. Sinks for washing food and cooking utensils and vegetable preparation g. Counter space for preparation of food—ample for several kitchen workers h. Bulk Storage: 1. Adjacent to kitchen for bulk purchased stock 2. Direct outside access for deliveries i. Area for garbage pails, cleaning equipment, garbage disposal, slop sink for mops j. Floor drain wash basin
2. Dining and Snack Service	a. Serving counter and steam tables b. Tray-cutlery-napkin stand	a. Dining area (Cafeteria-style—avoids service of total membership at one time) b. Location—adjacent to large lounge

SENIOR CITIZENS' CENTER

Need	Means and equipment	Design recommendations
	c. Drinking fountain	or auditorium for seated service of entire membership or other special events
	d. Cashier's table and chair	
	e. Dietician's desk-file	c. Counter for sliding trays
	f. Program material for groups	d. Aisle space to and from counter
	g. Serving carts—for service other than in cafeteria	e. Storage space for trays, cutlery, napkins
		f. Storage closet for program equipment (Dining room may be used outside of dining hours by special interest groups)
		g. Storage for serving carts
3. "Portable Home Food Service"*	a. Trays, steam carts	a. Storage for equipment
	b. Car, station wagon, truck	b. Direct access of vehicle to kitchen

* "Portable Home Food Service" is an auxiliary service to home-bound older people, now being offered by some centers, which brings one hot meal and often an additional meal per day into the home of older people in need of such service. It is also alluded to as "Meals on Wheels."

Meetings of groups and classes are a major part of any Center program. These groups may range from classes in creative writing to group discussions on current affairs. They may include a dramatics group or a Great Books course, or any

of a wide range of interests. An adequate number of rooms should be provided for these groups, for as the program develops, requirements will increase.

The number of meeting rooms will depend on

the size of the Center and the number of individual groups and classes.

Additional meeting space can be provided by using lounge and auditorium space for larger groups.

PROGRAM—GROUP MEETINGS, CLASSES, SPECIAL INTEREST GROUPS

Need	Means and equipment	Design recommendations
1. Music Groups		
Choral group	a. Table or desk, file cabinet	a. Soundproof room

12. Outdoor Recreation Areas	Varies with site and climate	
13. Parking 10 cars and pickup	2500	

MOBILE HOMES AND PARKS

LOCATION

The location of mobile homes and mobile home developments is usually controlled by zoning. Generally, zoning is based upon a land-use plan for the community, backed up by sound planning principles. However, the basis for mobile home zoning is frequently underlain by emotional considerations, rather than land-use planning.

Mobile homes, and mobile home developments in particular, have the reputation of being visually unattractive and of attracting lower-income housing and people. Communities tend to look at mobile homes as affecting property values and as tax liabilities. For these major reasons, mobile homes are often relegated to parts of the community which are undesirable for other uses or rural

out-of-the-way and out-of-sight places. Most of these areas have neither utilities nor community facilities but are selected to be developed as high-density living environments.

Mobile home developments are rarely allowed or encouraged in areas well suited for residential development. The normally accepted planning principles for residential land-use planning are to locate residential uses:

- in areas of compatible land use and surrounding environments;
- in areas with adequate utility and road support systems;
- in areas with reasonable convenience to community facilities;
- in areas of similar density such as a mobile home density of 4 to 7 dwelling units per acre, much like townhouses and low density apartments; and
- in areas of logical extension or infilling of the existing urban growth pattern.

These principles are often ignored with regard to mobile home zoning.

LAYOUT

The layout of a mobile home subdivision is normally a gridlike arrangement of parallel roads about 200 feet apart linked together by other local or collector roads. This arrangement is used because most development costs are determined by the amount of road frontage required for each lot. Lining the mobile homes up perpendicular to the road requires the least road frontage and is the most economical arrangement of lots.

Common facilities like swimming pools and community buildings, when provided, are usually centrally located within the development and are often located as a focal point along the entrance drive. Facilities are maintained by the developer or homeowners' association and each resident is charged a monthly rate for use and maintenance.

This section is from *Guidelines for Improving the Mobile Home Living Environment*, Office of Policy Development and Research, HUD, Washington, D.C., 1978.

4,000 SQUARE FEET LOT

4,050 SQUARE FEET LOT

4,125 SQUARE FEET LOT

4,250 SQUARE FEET LOT

Fig. 1

MOBILE HOMES AND PARKS

The typical subdivision lot consists of about 4,000–4,500 square feet of land with overall dimensions of 40 by 100 feet or 45 by 90 feet for single and 50 by 85 feet or 55 by 75 feet for double-wide homes. The lot fronts on a road built to local specifications for dedicated roads, but may not actually be dedicated to the municipality. The road right-of-way is usually a minimum of 50 feet wide and contains a 24- to 30-foot paved cartway. (See Fig. 1.)

INDIVIDUAL MOBILE HOME LOT

The mobile home lot is the land area, large or small, upon which the home is placed and which provides space for all of the belongings and activities of its occupant.

Required Functional Areas

The individual mobile home lot consists of six component areas which reflect the basic functions of the mobile home site—pad, parking, entrance, outdoor living, utility corridor and storage. The arrangement of these six functional components of the lot is somewhat variable, but typically looks like Fig. 2.

Fig. 2

The only component of this arrangement that is fixed is the utility side of the home which is always on the right side when facing the mobile home hitch. The other areas are variable, depending primarily upon the lot size and unit orientation on the lot.

Each mobile home lot is usually required, by ordinance, to provide the pad, parking area, outdoor living and storage areas. Existing standards vary, but typically define a minimum lot size and minimum yard areas, which does not give the flexibility of lot size required because of the highly variable size of homes. A minimum distance between homes and setbacks allows this lot size flexibility.

Convenience in Relationship of Use Areas

The arrangement of the six functional component areas of the lot should be determined by the floor plan of the home, the characteristics of each site, and the logical and convenient relationship of on-lot space. The sequence in which residents use the component areas should be reflected in

the lot arrangement. The occupant arrives at home in a car, makes his way from the car to the door and goes in. He lives in his house and occasionally moves outside of his home into the yard area as an extension of his living space. Logically, the parking area should be between the park entrance and door. The outdoor living area should be adjacent to the home and near one of the two entrances. (See Fig. 3.)

Fig. 3

Circulation—Hierarchy of Streets

Streets within mobile home developments should be grouped into four functional categories: (See Fig. 4.)

1. courts, places, culs-de-sac,
2. local streets,
3. subcollectors, and
4. collectors

Fig. 4 Street categories.

Courts, places or culs-de-sac are very minor residential streets, the primary purpose of which is to serve individual lots and provide access to local or higher forms of streets. A place may

be a dead-end, culs-de-sac street or court with no through traffic and with limited on-street parking. Local streets are generally short and may have culs-de-sac, courts, or occasionally two or three branching places. Usually, no through traffic should exist between two streets of a higher classification. The purpose of a local street is to connect traffic to and from dwelling units to subcollectors.

Subcollectors provide access to local streets and courts, places, or culs-de-sac and conduct this traffic to an activity center or to a collector street. A subcollector may be a loop street connecting one collector or outside arterial street at two points, or conducting traffic between collector streets or arterial streets.

Collectors are the principal traffic arteries within residential areas and carry fairly high traffic volumes. They function to conduct traffic to or between major arterial streets outside the residential areas. A well-planned neighborhood maximizes the number of mobile homes located on either local streets or courts, places, and culs-de-sac where there is no through traffic between streets of higher classification. Homes having direct access to subcollectors and collectors are allowable, but should be minimized. Local streets and courts are safe and desirable places to live; living areas are dominant and traffic movement is subordinate.

Only a single moving traffic lane is necessary on local streets or courts, while subcollectors and collectors should have two moving lanes. Frontage of living areas on entrance roads and collector streets should be minimized.

Street alignments should be based upon sight distance and probable roadway speeds using computation methods endorsed by the Institute of Traffic Engineers. Generally, a minimum practical curve radius in residential areas is 100 feet, with 30 feet acceptable on minor streets. Street alignment at intersections is especially critical. The preferred angle of street intersections is 90 degrees; for safety purposes, streets should never intersect at angles less than 80 degrees. When two streets intersect the same street, they should either form a through intersection or be offset by at least 100 feet.

Street gradients affect the visual character, safety and accessibility of the mobile home development. Generally speaking, grades between 2 and 7 percent are the most desirable; and a minimum of 0.5 percent is necessary on all curbed streets to prevent pooling of water. If gradients must be less than the minimum in very flat areas, special subgrade compaction and street construction controls are necessary. Streets of less than 2 percent grade are visually perceived as flat. Moderate slopes of 2 to 7 percent usually result in a more interesting street-scape and encourage more imagination in the siting of homes.

Streets should generally not exceed 12 percent grade, but on minor streets grades of up to 15 percent are acceptable. Where steep road gradients are unavoidable, care must still be taken to flatten grades at intersection areas; gradients within 100 feet of intersections should not exceed 10 percent, with 4 to 6 percent preferable in snow or ice areas for a distance of 50 feet.

Circulation layout determines the accessibility of the mobile home site within each development. In properly designed residential neighborhoods

MOBILE HOMES AND PARKS

without through traffic, travel distances from residences to collector streets are short, actual traffic speeds are low, lane capacity is not a controlling design factor, and inconvenience or short delay is a minor consideration.

In conventional single-family residential neighborhoods, traffic speed should be slow: approximately 25 miles per hour. In mobile home areas where density is higher, speed should not exceed 15 miles per hour. Momentary delays to allow other traffic to pass around parked cars is acceptable and it is customary to drive slowly to avoid children and pets.

Pavement widths should be determined by considering probable peak-traffic volume, parking needs, and limitations imposed by sight distance, climate, terrain and maintenance requirements. It is senseless for streets to be wider than absolutely necessary; excessive widths only increase development costs which are passed on to the lot renter or owner. Also, from an ecological point of view, avoiding excessively wide streets means less impervious surface which results in less storm water runoff. The special problem of delivering mobile homes to lots is not a major consideration in determining street widths. Spacing between the mobile homes and the grades from street to lot are of much greater concern. Movement of mobile homes from their original placement on a lot is uncommon. When homes are to be moved through narrow streets, notice may be given to remove parked cars from the street.

Where streets also serve as pedestrian walks, they should be built with a cartway 2 feet wider than otherwise required. All entrance streets and other collector streets with guest parking should be 28 to 30 feet wide; this provides for two moving lanes and a parking lane on one side. Collector streets without parking should be 24 to 26 feet wide. Minor streets with parking on one side should be 26 feet wide; and local streets, courts, plazas and culs-de-sac with no parking should be 20 feet wide. A 20-foot wide pavement is the minimum width which generally offers year-round utility and convenience where snow and ice control is necessary.

One-way streets may be allowed at 11-foot widths in the following situations: (1) adequate off-street parking is assured; (2) the climate is mild, and snow and ice control problems cannot be foreseen; (3) total loop length will not exceed about 500 feet; (4) no more than about 25 dwelling units are served; (5) adequate longitudinal sight distances can be provided; and (6) vehicle speeds may be reasonably expected in the 10- to 15-mile-per-hour range. A 16-foot-wide pavement may be a practical loop street alternative in difficult terrain where cross-pavement ground slopes are severe, where vehicle speeds will not exceed 10 miles per hour, and where other above-outlined considerations can be met. Under the various conditions outlined, the 16-foot-wide pavement can be functionally effective, but will result in a higher level of resident inconvenience than a wider pavement. Sixteen feet cannot be considered a desirable pavement width but must be conceded to be acceptable under certain conditions, where necessary to avoid destruction of natural features.

Street rights-of-way are a consideration unique to the mobile home subdivision development. Streets within rental parks simply aren't dedicated to the municipality since the entire park properly is owned by the park developer-operator. In order to achieve maximum density, a park developer

will usually retain ownership of roads and therefore does not have to meet local standards for roads or reserve a wide right-of-way.

Within the mobile home subdivision, the streets and street rights-of-way are dedicated or retained in the ownership of the homeowners' association.

When roads are to be dedicated, they have to meet the same standards applied to all roads within residential areas. This generally means that a 50-foot right-of-way is required. The resulting arrangement of space, small lots and wide rights-of-way, is comparatively wasteful of space. Space is still lacking where it is most needed (in the outdoor living area of individual homes) because lot sizes are still usually small. On the other hand, an excess of space is provided where it is needed least. The distance between homes on opposite sides of streets is sometimes 70 to 80 feet, a more generous spacing than is needed in a small lot development.

Street rights-of-way must be adequate to provide required street pavements, sidewalks, drainage facilities, and utilities as needed, when they are placed in the rights-of-way. Right-of-way widths are too frequently fixed uniformly by local ordinances, regardless of the actual space required to accommodate necessary improvements. Excessively wide rights-of-way waste land and result in avoidable maintenance costs to the municipality; a community realizes no tax revenue from street rights-of-way. This land would be better devoted to individual building sites rather than public right-of-way.

Sidewalks along the road edge in suburban residential areas are being provided less frequently than in the past, and the amount of pedestrian use varies. Placement of sidewalks immediately adjacent to the road isn't really a safe location unless curbs are provided. More elaborate developments have interior pedestrian paths linking logical origins and destinations such as clusters of individual homes to community facilities or to convenience commercial areas. Paths or sidewalks other than these are not necessary in low-traffic-movement areas.

Drainage facilities may include either grassed swales or curb gutters and subsurface storm drainage structures. Where roadside drainage swales are used, they normally require a right-of-way at least 10 feet wider than the pavement width. Thus if a 28-foot pavement is used and swales are located on both sides, a total right-of-way of 48 feet would be required. If streets are curbed, there may be no justifiable reason for right-of-way widths to be much wider than roadway pavements.

Dead-end streets must be provided with turn-around areas. Turn-arounds in most conventional single family subdivisions are cul-de-sac streets with a 75- to 80-foot-diameter paved area. It is fairly common in mobile home parks to eliminate the turning circle for streets with fewer than twenty-five homes, substituting a "T" or "Y" turn-around incorporated into a parking lot cluster. "T" and "Y" turn-arounds should utilize an 18-foot minimum radius on all turns. The residential dead-end turn-around is basically for automobile use, but larger vehicles must sometimes be accommodated. Residential streets will also be used, in decreasing order of frequency, by refuse collectors, delivery trucks, snowplows, moving vans and fire trucks. Experience has shown that circular paved turning areas 75 to 80 feet in diameter function very well.

Curbs along residential streets are usually justified for three reasons; (1) preventing the roadway pavement from breaking down, (2) controlling traffic from encroaching beyond paved surfaces, and (3) concentrating and channelizing storm-water runoff. Valid arguments have also been made against the use of curbs, making a clearcut answer difficult. Proponents of curbless streets regard curbs as both a needless expense and an ecologically unsound practice which disrupts natural surface drainage and requires expensive storm drainage facilities. Such facilities frequently concentrate storm water and produce water velocities which necessitate the collection of water in pipes and storm water systems. These conditions tend to minimize the amount of water infiltrating the ground and can cause a considerable amount of fast-moving water to leave the site and cause off-site flooding and erosion. Swales, an alternative to curbs, can collect water where velocity is slowed and allow it to be absorbed into the ground. Proponents of curbless streets also question the reliability of curbs as a safety measure, citing how easy it is for a vehicle to strike or go over a curb and out of control.

The decision to use curbs should largely be based on how effectively storm water can be removed from the site without causing harmful on- or off-site impacts. The feasibility of using swales should be explored as a preferred alternative over the use of curbs during the early planning phase. If curbs are used, the rolled curb may be more desirable due to the numerous crossovers required for frequent on-lot parking areas, yet its effectiveness in controlling traffic may be less. If curbs are not used, pavements can be prevented from unraveling by using a thickened-edge pavement, extending the base course beyond the paving surface by 6 to 8 inches, or using anchored steel edging flush with the pavement surface.

COMMUNITY FACILITIES*

The need for community facilities is related to the density of the development. Community facilities are especially important in small lot developments where private outdoor space is limited; they are somewhat less critical where lots are large enough to allow many activities in individual yards. At higher densities, community open space can compensate for small private exterior living space.

Regulations for community facilities and open space systems typically require that at least 8 percent of the gross site area be devoted to recreational facilities and that a community building, storm shelter, laundry and drying facilities, toilets, and a management office be provided. Depending on the size of the development, however, all of these facilities may not be desirable or necessary.

Tot lots and areas for children to play away from the mobile homes are especially necessary to minimize disturbance of the individual residents' outdoor living areas. In developments where lots are greater than 10,000 square feet, there is less dependence upon community space; but playground and park areas for large-scale activities are desirable as in any residential area.

Community areas should have a parklike atmosphere compatible with residential living environments. Community buildings and structures should also be designed in a manner compatible

* SOURCE: *Guidelines for Improving the Mobile Home Living Environment*, Office of Policy Development and Research, HUD, Washington, D.C., 1978.

MOBILE HOMES AND PARKS

with a residential living environment rather than a commercial development.

Public outdoor open space commonly consists of two types: "structured" and "unstructured" facilities. Structured facilities include formal playgrounds, golf courses, shuffleboard courts, tennis courts, swimming pools, and related facilities. Structured facilities are normally developed in a complex with a community building. Equally im-

portant are the unstructured public open spaces which can be as simple as open grass areas for spontaneous team games and other activities. The type of community facilities necessary for any mobile home development is determined by the occupants to be served. A family-oriented development may require more extensive outdoor open space for active recreation, whereas a retirement community may require less space but a greater

variation of activity areas. Community facilities commonly include such things as swimming pools, community buildings, vehicle storage areas, pedestrian paths, tot lots, and court games.

Community Building

A community facility which is common to most new mobile home parks is the community building.

Fig. 5 Mobile home park sketch plans.

MOBILE HOMES AND PARKS

It contains more than one activity and serves more than one function. Uses commonly built into a community building include: laundry facilities, meeting rooms, recreation rooms and, in the case of family-oriented parks, day-care centers. The building is normally constructed as part of a complex including structured outdoor recreation facilities, such as swimming pools and limited off-street parking. Community buildings should be designed with a residential character harmonious with the mobile home development. When constructed and managed properly, the community building can be a major asset to the mobile home environment. The key word becomes "management," for after the mobile home development is established and the community building is constructed, it is the responsibility of the homeowners' association in subdivisions, and the operator in parks, to maintain the structure and operate the activity programs.

A secondary, but very important, function of the community building is that of storm shelter for mobile home residents. In areas of the country where dangerous storms might occur, a structurally adequate community building of ample capacity must be provided for the residents' safety.

The Mobile Home Manufacturers Association recommends that approximately 10 to 15 square feet of floor area per mobile home unit should be provided.

Common Vehicular Storage Area

Much of the clutter and disarray in mobile home parks is due to the lack of a defined storage area for seldom-used vehicles or recreational vehicles. Provisions for storage of these vehicles should be included in the mobile home development, especially where lots are small. In many mobile home parks, residents have more leisure time than their conventional housing counterparts; recreational equipment, snowmobiles, boats, and travel trailers are sometimes abundant. Recreational vehicles generally take up too much space to be stored on each individual home site. Common areas accessible to all residents of the development are necessary to store such vehicles or equipment. The storage area should be separated from the living areas of the site and should be a gravel or hard surface area enclosed by a secu-

rity fence and adequately screened from sight. At least one storage space should be provided for every 19 mobile homes.

Swimming Pools

Swimming pools do much to enhance the image of a mobile home community. In fact, most high-quality mobile home parks include a swimming pool or some equivalent structured recreational facility. The generally isolated location of mobile home developments suggests that such a facility is desirable, especially under certain climatic conditions and for specific segments of the mobile home market. Swimming pools are usually located near a community building and other structured facilities, and should be designed to accommodate the anticipated usership without undue crowding. An estimate of participation rate during typical summer weekends provides the basis for determining an appropriate pool size. This rate of participation varies with the expected population characteristics of the development. Approximately one-quarter of the persons at the pool will be in the water at any one time, and the pool should be designed to provide 10 to 15 square feet of water surface for each wader and 30 square feet for each swimmer. Deck area equal to or larger than the pool surface area should be provided. Most participants also desire a large, fenced-in turf area of equal size for sunbathing.

A general rule of thumb for estimating required pool area is to provide 3 square feet of pool surface for each mobile home lot. (This standard assumes 2 potential participants per home, 20 percent participation rate, 25 percent of actual participants in pool at any one time, and 30 square feet of surface per swimmer.)

Tot Lots and Playgrounds

Tot lots are small playgrounds consisting of several pieces of play apparatus, swings, or climbing equipment provided especially for use by young children. They should be located close to the homes which they serve or within the community recreation area where they can be easily observed and supervised. Ideally, a small tot lot could be established for each grouping of homesites so

that children could use them without crossing collector streets in the development. Tot lots also work well when located adjacent to adult recreation areas so that children may be observed by adults using other facilities.

Playgrounds are somewhat larger in scale than tot lots and are normally oriented to elementary-school-age children. They should have safe apparatus which provide opportunities for children to use a variety of motor skills. Such equipment can include: tire or other flexible-seat swings; seesaws with tire safety stops; climbing arches or other apparatus on "soft" surface; and splinter-free climbing blocks.

Court Games

Basketball and tennis courts are popular facilities for adult recreation. They can often be incorporated into a centralized recreation clubhouse complex where they are easily accessible via streets and pedestrian paths. Both facilities require much space, serve a limited number of people at any one time, and can benefit from night lighting which increases the number of people who can be served.

General Court Games

- Provide a variety of facilities to serve various age groups including:
 - basketball courts (hard surface)—50 users per half court, daily capacity
 - Volleyball (in lawn area)—72 users per court, daily capacity
 - shuffleboard (hard surface)—20 users per court, daily capacity
- Lighting for night use of court areas is desirable and will increase daily capacity by 20 to 30 percent.

Tennis Courts

- Provide a fenced, low-maintenance, all-weather (hard-surface) court.
- General capacity is 20 participants per day per court.
- Lighting for night use is desirable and will increase capacity by 40 percent.

OFFICE, MOBILE HOME PARK

NOTE: SIZE AND FACILITIES SHOWN FOR THIS OFFICE BUILDING IS BASED ON HYPOTHETICAL CONDITIONS AND IS NOT MEANT TO BE AN ILLUSTRATION OF A MODEL OFFICE FOR ANY PARK.

ANY GIVEN PARK HAS CONDITIONS WHICH DICTATE WHAT AN OFFICE BUILDING SHOULD HAVE TO FUNCTION PROPERLY, THE FOLLOWING CONDITIONS SHOULD BE CONSIDERED---

- 1 PARK ADMINISTRATION AREA
- 2 WAITING AREA
- 3 PUBLIC AREA
- 4 PARK INFORMATION CENTER
- 5 PUBLIC PHONES
- 6 PARTS & SALES SERVICE
- 7 STORAGE
- 8 ELECTRICAL & MECHANICAL RM.

OTHER THAN SIZE OF BUILDING, TYPE OF CONSTRUCTION AND AREA LOCATION, SOME OF THE FACTORS WHICH DICTATE SIZE OF AREA REQUIRED ARE: REQUIREMENTS OF ELECTRIC, PHONE, GAS & WATER COMPANIES & LOCAL CODES FOR INCOMING SERVICES, METERING, PROTECTION & SUPERVISION FOR THE PARK UTILITIES, AS WELL AS VENTILATION, SPACE & WATER HEATING, ELECTRIC PANELS, ETC., FOR THE BUILDING ITSELF.

ADDITIONAL AREA REQUIREMENTS MAY BE: CENTRAL LIGHTING CONTROL STATION AND CENTRAL T.V. ANTENNA RELAY STATION.

NOTE: ALL ABOVE INFORMATION MUST BE DETERMINED LOCALLY BY THE PROSPECTIVE PARK OWNER. THERE ARE NO NATIONAL AVERAGES OR A "TYPICAL" OFFICE BUILDING TO FIT ALL CONDITIONS.

1. INTRODUCTION

A Youth Hostel Described

A youth hostel provides for young people on their travels what a hotel provides for adults: a place to sleep, wash, and eat. But whereas a hotel segregates people—in private rooms and at private tables—a youth hostel brings them together; it is a meeting place at which young people of different nationalities, social backgrounds and opinions can meet and come to know each other.

The simplest youth hostel, in a country district frequented by walkers or climbers, will provide only the basic requirements of dormitories, wash-rooms, sanitary installation, and a kitchen in which travellers can prepare their own meals. On the other hand, a large modern youth hostel, in a city or main tourist center, will offer comfortable bedrooms with four to eight beds, hot shower baths, recreation rooms, a restaurant or cafeteria, and other facilities. (See Fig. 1.)

Each youth hostel is in the charge of adult houseparents or 'wardens' (generally a married couple) who have an educational as well as an administrative function; their task is to weld the group of young strangers under their roof into a friendly and happy community for the brief period of two or three days. The charge for accommodation is kept to the minimum consistent

with adequate standards. For this reason simplicity is the rule—there are no servants, and visitors normally take a share of the domestic duties in the hostel; beds are equipped only with mattress and blankets, each visitor bringing his own sheet sleeping bag in place of sheets; furnishing is simple though it may be in good taste.

'Youth' is a word which cannot be rigidly defined, and there are few countries in which a strict age limit is applied. Preference is generally given, however, to visitors aged under 25, while 10 years is considered the minimum age for international usage of hostels.

In order to exercise some control over the use of hostels, admission is restricted to holders of a membership card, but a card can be obtained for a very modest charge (graded according to age) and no discrimination is shown against any applicant on grounds of religion, politics, race, colour, etc. Membership cards issued in any country within the International Youth Hostel Federation are accepted at youth hostels in every other country.

Consequently, hostels should have a certain uniformity, so that, in whatever part of the world it may be, the youth hostel will provide accommodation acceptable to all visitors. Thus for instance, in Japan, western style beds and chairs are to be found alongside the traditional pillows, cushions, and beds placed directly on the floor. At the same time, it is important that each country preserve its individual customs and national characteristics,

as these are often the very things which attract visitors. The youth hostel must never be a form of standardized barracks which could be produced in any country and be repeated throughout the world. The converse in fact should be the criteria: no two hostels even in the same country should be identical, in order that each hostel visited will be a new experience. Within this principle, the practical arrangements of spaces and hygiene facilities can, and should, conform to a common minimum standard:

MINIMUM AND NORMAL STANDARDS FOR YOUTH HOSTELS

(adopted at the 28th Conference of the International Youth Hostel Federation, 1970)

Minimum Standards (Obligatory)

Every Youth Hostel must provide:

- Supervision by a warden or other suitable adult person who shall be responsible for the well-being of the person using the hostel.
- Separate dormitories for men and women, with separate entrances (but family rooms may be offered for parents with young children). Dormitories must be equipped with beds, each with a mattress, a pillow, and a sufficient number of blankets according to the climate.
- Separate sanitary installations (toilets and washing facilities) in adequate numbers for men and women, kept in clean and hygienic condition.
- A members' kitchen, equipped with cooking stoves, pots, pans, etc., or some simple facilities for cooking meals. Facilities enabling the hostel staff to provide meals at reasonable prices may also be provided.
- A common room, terrace, or other place (depending on the climate) in which guests can meet and get to know each other.

Additional Facilities (Optional)

Dependent upon the size and function of a youth hostel, other accommodation will be required which may include the following:

- (a) A baggage room
- (b) Living accommodation for staff
- (c) A lockable cycle store
- (d) A heated and ventilated drying room for the drying of wet clothing
- (e) A kitchen in which the warden and/or staff can prepare meals for supply to the hostellers; also food stores, and facilities for catering staff
- (f) A separate small room (or rooms) for leaders or instructors
- (g) A sick room (alternatively the leader's room can be used in the case of sickness)
- (h) A room in which hostellers can wash, dry, and iron clothes
- (i) A room in which the warden (or hostel staff) can launder hostel linen
- (j) Additional common rooms which can also be used as dining rooms and as classrooms for school parties
- (k) A reception office and store where the warden can receive and book in hostellers
- (l) Accommodation for specialist equipment as required depending on the location: ski store, boat sheds, stables, etc.

In the early days of the youth hostel movement many very simple hostels were set up in whatever property was available, such as old cottages, huts, old schools, and farm buildings. This type of simple accommodation is still employed in many parts of the world, especially in those areas where the population is thin and there is a degree of isolation.

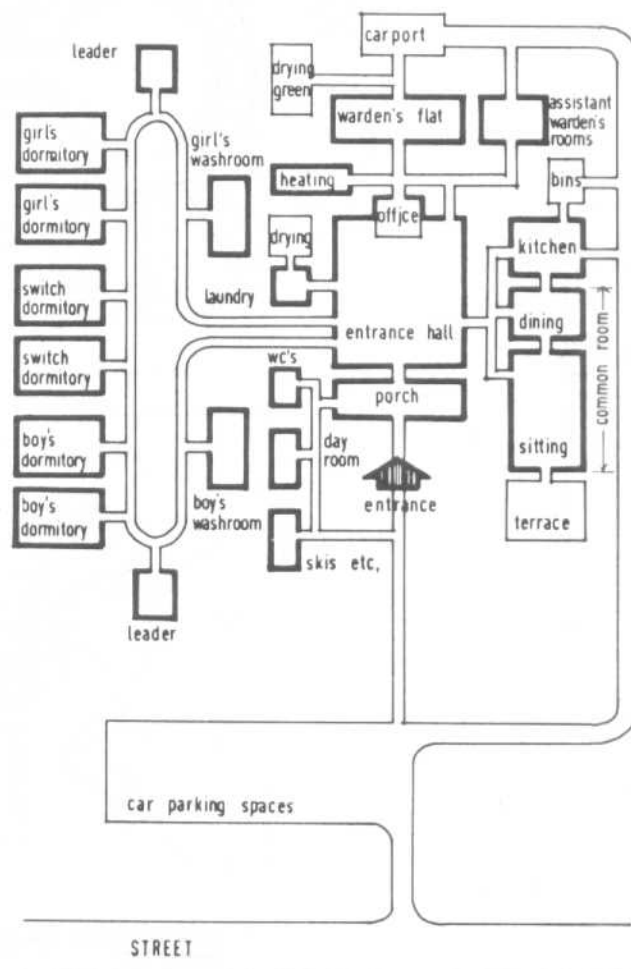

Fig. 1 Diagram showing the relationship between the elements of a modern youth hostel.

INTRODUCTION

This section has been prepared to assist in the designing of a new hostel or in the conversion of an existing building into a hostel.

Each type of room necessary in a hostel is described and all the various features relative to each room are indicated.

The information in this section is based on the physical standards for hostels adopted by the American Youth Hostels in 1962 and on the national building code of National Board of Fire Underwriters.

All the computations are approximate and they must be modified to suit actual conditions. All local or state building codes which are more stringent than the information in this section will take precedence.

Figure 2 illustrates the relationship that should exist among rooms. Entrance through the foyer into the common room; then, access to the boys' and girls' bunk rooms, preferably through a hall. The toilets should be located directly off the bunk rooms, but it is also desirable to have access to them from the hall, so that the bunk room does not become a passageway.

Fig. 2 Flow diagram.

The common room and dining room may be combined in small hostels and provides a big, flexible space for recreation. The kitchen, located off the dining room, should be large enough to handle group cooking activities. If possible, the kitchen should have direct outside access for ease of food and garbage transport.

A Trail Hostel Design Manual, American Youth Hostels, Inc., New York, N.Y.

COMMON ROOM

Room Area

A minimum of 15 sq ft per person is required. For combination dining and common room, 22 sq ft per person should be allowed. (See Table 1 and Fig. 3.)

TABLE 1. Room area chart*

Number of people	Common room, min. sq ft	Dining and common room, min. sq ft
10	150	220
15	225	330
20	300	440
25	375	550
30	450	660
35	525	770
40	600	880

*These are minimum room sizes. More space is always desirable.

Fig. 3 Dining-common room. Typical layout for 30 people.

DINING ROOM

Room Area

A minimum of 12 sq ft per person for dining room is required. For a combination dining and recreation room, minimum of 20 sq ft per person should be allowed. (See Table 2.)

TABLE 2 Dining room (only) room area chart*

Number of people	Area needed, min. sq ft	Window area, min. sq ft
8	100	8
10	120	10
12	144	12
16	192	16
20	240	20
24	288	23
28	336	27
30	360	29

*These are minimum room sizes. More space is always desirable.

Fig. 4 Typical dining area for 16 people.

KITCHEN

• Add units together to form larger kitchens

- Should have door to outside handy for garbage or food deliveries
- Should try to line up sinks for economical plumbing
- Should have window or electrical fan for range ventilation

TABLE 3 Schedule of Kitchen Fixtures (Minimum)

Number of people	Sinks	Range burners	Refrig., 9 cu ft	Ovens
10	1	3	1	1
15	2	3	1	1
20	2	4	2	1
25	2	5	2	2
30	3	6	2	2
35	3	7	3	2
40	3	8	3	2

BUNK ROOMS

TABLE 4 Room Area Chart

Number of double bunks	Number of people	Min. area needed, sq ft	Min. window area desired, sq ft
2	4	120	15
4	8	240	30
6	12	360	45
8	16	480	60
10	20	600	75
12	24	720	90
14	28	840	105
16	32	960	120

Must include extra space for blanket and mattress storage in closet.
Minimum ceiling height is to be 8 ft.

Fig. 10 Typical toilet layout. Note back-to-back placement of plumbing fixtures for economy; common plumbing wall for ease of plumbing access; washroom area separate from toilet area for better usage; water closets in separate compartment for privacy; screen at entrance door to shield interior.

HOUSEPARENTS' APARTMENT

• Houseparents' apartment should be located next to and connected with the hostel common room for control.

• A small office is a good connection to the hostel from the apartment. It should overlook the hostel entrance, if possible.

• A separate outside entrance should be provided.

TABLE 6 Minimum Room Size Schedule

Room	Area, sq ft

**SITE PLANNING AND SUBDIVISION
LAYOUT**

Site planning in its narrow sense involves the disposition of space for appropriate uses; the positioning of structures to provide effective relationships (well-proportioned masses with attractive outlooks and good orientation); the provision of access to structures in an expeditious, attractive, and safe manner; the design of the services, walks, streets, parking facilities, drainage, and utilities; the preservation of the natural advantage of the site, and its enhancement by landscaping.

In its larger sense, site planning involves consideration of the site in relation to the physical pattern and economic growth trends of the larger area of which it is a part. An analysis of the area should be made based on population growth, family formations, family size, housing inventory, income levels, schools, taxes and assessments, transportation and traffic patterns, and directions of growth. An analysis of site development costs should be made in terms of densities, housing types, construction types, topography and grading, and local requirements with regard to zoning, subdivision regulations, and utility services. This analysis may be made as a basis for site selection or as a basis for determining the most appropriate use of a particular site. For large sites involving several types of housing, commercial or industrial uses, schools, and churches, more extensive analyses may be necessary. For small sites forming parts of neighborhoods already established, the analysis need not be as comprehensive.

A subdivision site plan can be made for a complete community, involving all types of land use found in a typical town or village, or for a neighborhood, usually considered to be a homogeneous area large enough to support an elementary school, or for a segment of a neighborhood. The

Fig. 1. Principles of neighborhood planning
Courtesy Urban Land Institute

1. **Size.** A residential unit development should provide housing for that population for which one elementary school is ordinarily required, its actual area depending upon its population density.
2. **Boundaries.** The unit should be bounded by arterial streets sufficiently wide to facilitate traffic by-passing the neighborhood instead of passing through it.
3. **Open Spaces.** Small park and recreation space, planned to meet the needs of the particular neighborhood should be provided.
4. **Institution Sites.** Sites for the school and other institutions having service spheres coinciding with the limits of the unit should be suitably grouped about a central point or common, and combined with the neighborhood recreation area, usually.
5. **Local Shopping Center.** If warranted by the population to be served the local convenience shopping facility should be located at the edge preferably at an arterial traffic junction and adjacent to similar commercial districts, if any, of adjoining neighborhoods.
6. **Internal Street System.** The unit should be provided with a special street system, each highway being proportioned to its probable traffic load, and the street net as a whole being designed to facilitate circulation within the unit with good access to main arteries, and to discourage its use by through traffic.

Sites are provided for parks, playing fields and recreational areas.

Church sites are provided in convenient locations.

There is a central shopping area, with off-street parking.

Two school sites are provided, reasonably accessible from all parts of the neighborhood. The Catholic school is off-centre because it also serves adjacent neighborhoods.

"Through" arterial highways, of adequate width, are separated from local service roads by limited access planted strips. Thus both "local" and "through" traffic are safeguarded. There are feeder roads for bus routes. Local residential streets are designed in such a way as to discourage "through" driving, yet remain adequate for local purposes.

At the corners of the area, there are intersections designed to keep "through" traffic moving.

One-family housing is created in an aesthetic as well as a functional setting. Set-backs are arranged to allow for a "rhythmic variation". A buffer strip separates housing from an adjacent industrial zone.

There are also apartments and row housing in a variety of types.

A neighborhood "focus" of larger buildings and open space is included as an essential ingredient of a well-designed residential area.

Fig. 2. Example of well-planned neighborhood
Courtesy Urban Land Institute

principles of neighborhood planning are illustrated in Fig. 1; an example of a well-planned neighborhood is shown in Fig. 2.

Housing types

It is no longer considered good practice to limit housing within a subdivision to one type and price range. For sites of fewer than 100 houses the range of types should be restricted but the range in price should permit some variation, the degree of difference being reduced as the size of the site diminishes. For larger sites not only may the types of single-family houses be varied, but rental housing of either high-rise or garden types may be included where zoning permits. Apartments and town houses (row houses in small groups) often provide a very satisfactory transition between the commercial (shopping) areas and the less dense residential areas.

Single-family housing: Lot sizes for the single-family detached house are wider now than they were 30 years ago; 60 ft is considered the minimum width and 70 to 80 ft is more usual. This has come about because of the popularity of the one-story house

with large glass areas and provisions for outdoor living with a reasonable degree of privacy. Devices such as patios and courts and fenced-in areas are used to provide privacy when lot sizes are small. An example of a typical one-story subdivision house of better than average design is shown in Fig. 3. The split-level house is also popular in subdivision work because it provides the economy of the two-story house but requires less stair climbing.

Row houses or, as they are now called, town houses are finding many advocates because of their economical use of land and low site-development costs. When developed with not more than 8 or 10 units (preferably fewer) in one group and located around a court, cul-de-sac, or loop street, the monotonous appearance usually associated with such housing disappears. Lots should be 20 to 25 ft wide; wider lots with side yards should be provided at the ends of the groups. Garages should be provided either within the house structure itself or as a one-story attached structure, often a carport, at the front of the house. An example of the variety possible within this

housing type is shown in Fig. 4; see also Fig. 16.

Rental housing, for more attractive appearance, is now built at lower densities and with more emphasis on open space; it often includes such club-like features as swimming pools and tennis courts. Densities of 15 to 25 families per acre and coverages of 15 to 25 per cent are standard in well-designed garden apartment developments. Garden apartments are usually two stories high and should not be higher than three stories (Fig. 5). High-rise elevator apartments should restrict land coverage to 10 to 15 per cent. The trend in apartment design is toward larger rooms, more storage, and other facilities in keeping with those of single-family housing.

Lot sizes and development costs

The cost of raw land and the cost of installing streets and utilities has greatly increased in recent years. At the same time, as previously noted, lot widths have markedly increased. In order to keep the cost of the developed lot from rising to prohibi-

Residential

SITE PLANNING

Fig. 3. One-story house plan
Courtesy National Association of Home Builders

tive levels, site planners have resorted to the "superblock." This is typically a long, shallow block (600–800 ft by 200–250 ft) which reduces the number of cross streets and eliminates the need for utilities in them. Typical lot depths are thus likely to be $1\frac{1}{2}$ to 2 times their width. Deep superblocks, penetrated by culs-de-sac or loop streets, are also used. Further economies in development costs result from the use of a functional street system, as described later on, which permits most of the streets to be built to the most economical specifications (see also Fig. 15 and the discussion of the cluster plan).

Basic data for estimating lot costs are given in Tables 1 and 2.

Streets

Conformance with the master street plan for the city is usually a requisite for any subdivision plan. As a rule, however, this requirement applies only to major streets. It is a factor which should be given consideration in the initial analysis of the site since it is undesirable to have major streets traverse a residential area. At the boundaries, however, major streets may be an asset if they provide good access to other areas in the community.

Fire protection should be considered in determining the street pattern. Some of the problems to consider are hydrant location, culs-de-sac turn-arounds, access to buildings in multifamily projects and commercial areas, radius of curvature of curbs at intersections, and similar problems.

Streets are necessary evils in a neighborhood or smaller subdivision; they are intended primarily to provide access to and circulation within the area. Streets serving other purposes (arterial streets) should

Table 1. Lot sizes and dwelling densities

From Community Builders Handbook, Urban Land Institute.

Dwelling Unit Type	Lot Dimensions Per Dwelling Unit in Feet	Net Density* Dwelling Units/Acre
<i>Single Family</i>		
Detached houses -----	100 x 200	2.0
	80 x 160	3.5
	70 x 140	3.3
	60 x 125	4.3
	50 x 100	6.5
Semi-Detached houses ----	30 x 125	8.7
	26 x 125	10.0
Row houses, two-story ----	20 x 100	16.3
	16 x 100	20.4
Garden Apartments, two-story -----		15 - 25
Garden Apartments, three-story -----		25 - 35
Apartments, multiple story to 12 stories -----		50 - 85

* Net density represents the number of dwelling units per acre of land within the site, after deducting 25 per cent of the site for allocation to streets, park and recreation areas.

Gross density is computed on the basis of net land area plus area devoted to streets and other nonresidential uses and one-half of bounding streets and one-quarter of bounding street intersections.

Table 2. Lot areas and dwelling densities

Dwelling Unit Type	D.U.'s per Net Acre	Assumed Average Sq. Ft. of Lot per D.U.
Single-family	1	40,000
" "	2	20,000
" "	3	12,500
" "	4	10,000
Two-family	6	6,000
Row house	15	2,600
Garden apartment*	25	1,600
Multi-story apartments*	50	800

* The more intensive the use of land, the greater need there is for recreation space, wider streets and sidewalks, shorter blocks and off-street parking. In multi-family development careful consideration must be given to land coverage and open space needs. High density, multi-family intrusions into single family residential development must be avoided. Apartment buildings must be spaced and located within the project so as to provide transition between residential land uses. The developer of multi-family areas has a responsibility in making such sections of his city fitting, appropriate and serviceable to his community.

bound rather than penetrate the area. The street pattern within the area should be designed to discourage through traffic. The widths of the interior streets should be consistent with their function and the density of housing they serve and should be no greater than necessary, in the interest of safety and economy of installation and maintenance. Subdivision street types are illustrated in Fig. 7. Collector streets, those carrying traffic from minor streets to arterial streets should have a paved width of 36 ft, consisting of two moving lanes and two parking lanes. Minor streets, depending on the off-street parking provisions and the density of the area they serve, should be 26 ft wide for single-family detached houses and 32 ft wide for row houses and apartments. Short access streets, such as culs-de-sac or loop streets, may have mini-

mum paved widths of 20 ft. Culs-de-sac should terminate in a turning circle not less than 80 ft in diameter between curbs. Rights-of-way should be 60 ft wide for collector streets, 50 ft for minor streets, and 40 ft for culs-de-sac and minor access streets. A cul-de-sac should not be in excess of 500 ft in length (see Fig. 8 and Table 3).

The use of the "T" intersection of minor streets and of minor with collector streets, with at least a 125-ft separation between opposing intersections, offers a device to reduce through traffic within a subdivision area and improve the safety conditions (Fig. 9). Slight jogs in the alignment of streets are not desirable.

Where the subdivision borders on arterial highways or streets bearing heavy traffic, houses should not be entered directly

from such streets. Instead, the lots should be backed up to the highway and heavy planting should be provided along the rear-lot lines. Or a local access road should be provided parallel to the highway and screened from it by planting (Fig. 10). Either method serves to reduce the number of street intersections with main traffic ways to a minimum and to keep driveways off the main highway.

Sidewalks

The design of sidewalks is often governed by local regulations. Sometimes they may be omitted in low-density areas of single-family detached homes. Some jurisdictions permit installation on one side of the street only, others require sidewalks within certain distances of schools, usually inside the zones beyond which school busses operate. Higher-density areas (more than 5 families per acre) and streets carrying other than local traffic usually require sidewalks on both sides of the street.

Four feet is the customary design width for sidewalks. When combined with the curb they may sometimes be as narrow as 3 ft 6 in.; in commercial areas they should be much wider. When sidewalks are separated from the curb by a planting strip, the strip should be at least 3 ft wide to provide for snow removal; if trees are included it should be at least 7 ft wide (see Fig. 8 and Table 3).

Curbs

The rolled curb is more economical than the straight curb and does not require cutting at driveways. It is not recommended however on steep grades or in hillside developments. When used, rolled curbs should be molded into straight curbs at intersections to discourage corner cutting. The suggested radius of 15 ft for curbs at right-angle intersections discourages speeding and is intended for intersections of minor streets. Cuts in straight curbs for driveways should provide for 3 to 5 ft radiuses and a 9 or 10-ft wide driveway.

Lot layout

The layout of the lots in a subdivision can make the difference between an attractive and an unattractive development, also the difference between an economical and an uneconomical project. Good and poor lotting practices are illustrated in Fig. 11 and methods of lotting around culs-de-sac are shown in Fig. 12.

Topography

Topography can influence the character of a subdivision. Hilly land, with grades steeper than 10 per cent, may be developed for low-density, higher-priced homes,

SITE PLANNING

or for multifamily projects of relatively low density, but it is rarely adaptable to small lots and lower-cost homes. Flat land, because of the difficulty of obtaining good drainage for sewers and storm drains, may also not be suitable for low-priced homes. Gently sloping land without drainage pockets or swampy areas or underlying rock is best for low-cost development. Where public sewerage is not available the character of the soil is an important factor and may even determine the lot sizes. Soil seepage tests are usually required by health departments where septic tanks and disposal fields are installed. If public water service

is not available and individual wells must be used, this too may affect lot sizes. Community water and sewerage systems should be provided wherever possible in these cases; wells and septic tanks should be used only as a last resort.

The nature of the topography will affect the street pattern. Streets should be laid out so as to avoid steep grades, excessive cut and fill, and to provide buildable sites with good surface drainage. In general, streets should follow natural drainage lines or ridge locations. On side hill locations, they should cut across the contour lines, in order to avoid cut and fill operations.

Steep grades can be reduced on hilly land by running streets diagonally across the contours.

Surface drainage: Not only must the entire site be graded for proper drainage, but each individual lot and block must be separately and carefully considered. Examples of proper grading for surface drainage of lots and blocks are shown in Figs. 13 and 14.

Off-street parking: For single-family detached houses parking is usually provided in an attached garage or carport. The set-back from the street is normally sufficient to permit overflow parking in the driveway. Apartments are usually provided with parking bays or courts located reasonably near the building entrances. Suggested designs for such parking areas are shown in Fig. 15 (see also sections on "Apartments" and "Automobiles: Parking").

For parking areas at neighborhood shopping centers see sections on "Shopping Centers" and "Automobiles: Parking."

Recreation areas are essential and should represent at least 5 per cent of the residential area and more where the lots are small (see sections on "Apartments" and "Recreation.") Playgrounds for small children ("tot lots") may be quite small but they must be widely dispersed throughout the site. Playgrounds for older children are best provided by enlarging the school site and its playground. This provides an adequate recreation area in one place and simplifies supervision and maintenance. Wherever possible, recreation areas should be maintained by the local government. When recreation areas provided by the developer are not taken over by the local government, they must be maintained cooperatively by the residents through a neighborhood association, as discussed farther on.

SUBDIVISION REGULATIONS

Subdivision of the land is a permanent change which determines the use of the land for at least a generation and profoundly affects the surrounding area. The public interest is thus directly concerned and local governments now generally exercise strict controls over this important function. Most municipalities, many counties, and some states now have subdivision regulations. These generally require conformance with established standards of design and construction such as:

Streets: location, types, rights-of-way widths, pavement widths and specifications, grades, intersections, curvatures, alignments, curbs, gutters, sidewalks

Table 3. Design of local residential streets

From Traffic Engineering Handbook of Institute of Traffic Engineers and Home Builders Manual for Land Development of National Association of Home Builders.

Speed: Based on maximum of 25 m.p.h. in accord with Uniform Vehicle Code recommendation. Recommendations will be reasonably satisfactory if some speeds exceed 25 m.p.h. a little.		
	Single-family Units	Multi-family Units
Street Width:	50 feet	60 feet
Pavement Width:	26 feet	32 feet
Curbs:	Straight curb recommended	Same
Sidewalks		
Width:	4 feet minimum	Same
Set-Back:	3 feet minimum if no trees, 7 feet minimum with trees	Same
Horizontal Alignment:	200 feet minimum sight distance	Same
Vertical Alignment:	6-8 per cent maximum grade desirable 3-4 per cent per 100 feet maximum rate of change	Same
Cul-de-sac:	400-500 feet maximum length	Same
Turn-arounds:	40 feet minimum curb radius without parking	Same
	50 feet minimum curb radius with parking	Same
Pavement Surface:	Non-skid with strength to carry traffic load	Same

Blocks: length, width, crosswalks, utility easements

Lots: size, shape, minimum dimensions

Open spaces: size, type

Utilities: storm and sanitary sewers, culverts, bridges, water service; monuments

Names: of area and streets; street numbers

PROTECTIVE COVENANTS

Covenants, sometimes called deed restrictions and sometimes protective covenants, are usually drafted by the subdivider of an area to provide land use regulations for the entire area, either supplementing those of the zoning ordinance or in lieu of it. They are, or should be, recorded and made superior to the lien of any mortgage and are intended to preserve

the physical, economic, and esthetic qualities of the subdivision in the interests of the subdivider in aiding his development program and of the purchasers in protecting their investment. Enforcement should be delegated to a home owners or neighborhood association.

Protective covenants, being a contract or agreement between private parties, may include provisions which go well beyond the public health, safety and welfare provisions to which zoning regulations are limited. These may include any or all of the following:

Architectural control—Usually provides procedure for the review of designs for new construction and alterations for approval by a designated individual architect, or committee of the neighborhood

Fig. 7. Subdivision street types
Courtesy Housing and Home Finance Agency

Cross-section A. Provides two-way traffic with parallel parking on both sides. For collector streets in developments of one-family detached houses and for minor streets in apartment developments.

Cross-section B. Provides two-way traffic and one continuous lane of parallel parking on one side or parallel parking alternated on either side of the street. For minor streets in developments of one-family detached houses.

Cross-section C. Provides two-way traffic and drainage with all parking on individual driveways. For streets in country home developments.

Cross-section D. Marginal access street paralleling an arterial highway. Provides two-way traffic, one lane of parallel parking, safe access to properties and protection from through traffic.

Cross-section E. Provides separated two-way traffic with parallel parking on both sides. For use as collector streets of the boulevard and development entranceway types.

association, as to conformity with the esthetic character of the area. Use and size of the structure may be limited more severely than required by the zoning ordinance. In particular, minimum sizes may be established. Size limitations may refer to height, number

of stories, area, volume, or cost; the latter is not an effective device because of fluctuation of building costs. Lot sizes and setbacks greater than required by the zoning ordinance may be called for. Landscaping and fences may be con-

trolled as to placement and height. This may be desirable for various reasons: to ensure visibility at street intersections, to prevent interference with surface drainage, or to preserve a desired esthetic character for the subdivision as a whole. Nuisances: Various undesirable usages may be prohibited such as business, farming, mining, signs, outdoor garbage or refuse incineration, tents, trailers, etc.

Covenants usually run with the land for a definite term of years, with provision for renewal unless terminated or modified by agreement of the property owners affected. Restrictive covenants based on race or religion have been declared unconstitutional by the Supreme Court of the United States.

HOME OWNERS ASSOCIATIONS

Home owners associations or neighborhood associations, as they are sometimes called, are usually established by the subdivider to provide a means for carrying out certain community functions, such as the maintenance of recreation areas and the enforcement of protective covenants. The management of the association is usually turned over to the owners of the subdivided land when sales progress to a predetermined ratio. The association is usually established as a corporation with a charter from the state and reference to it is made in the protective covenants or deed restrictions. To be effective it should have the power to assess the property owners to obtain the funds necessary to carry out its functions. It should provide for representation of the owners in the selection of the management in an orderly manner through well-drafted bylaws. The functions of the Association can be any of the following:

Action to enforce the protective covenants in case of violation by any property owner, or where continuing action

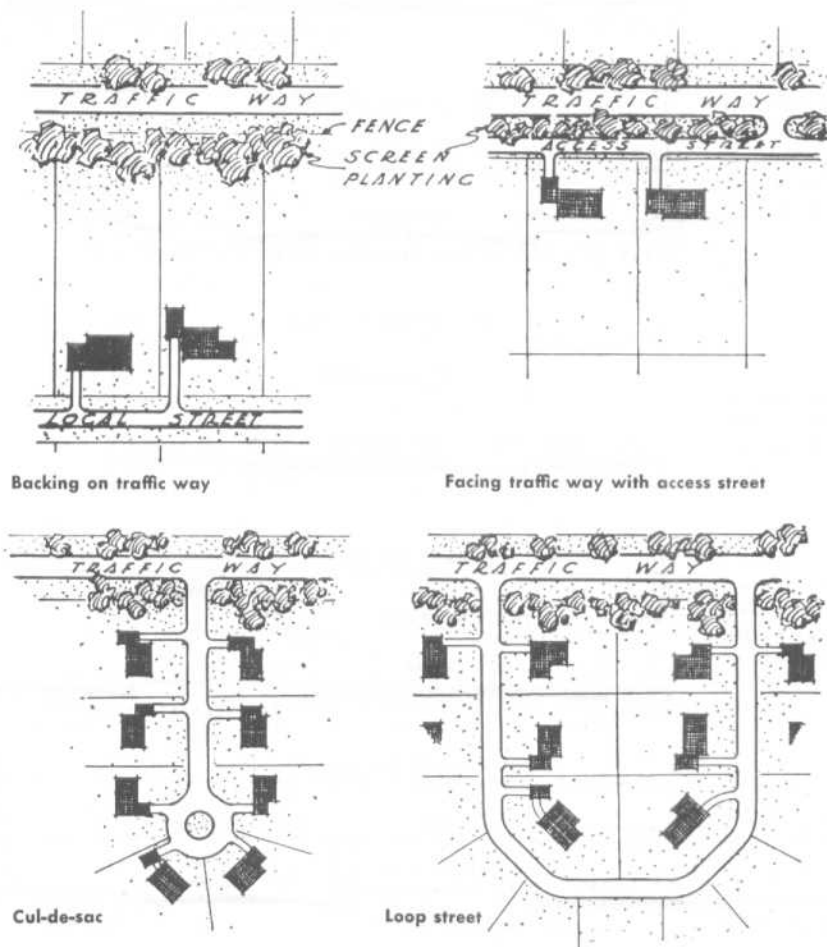

Fig. 10. Methods of subdividing along heavy traffic ways
Courtesy Urban Land Institute

is required as in the operation of an architectural control of design.

Operation of community facilities, such as club house or community center and recreational facilities such as playgrounds, swimming pools, tennis courts, or golf courses.

Maintenance of common land such as cul-de-sac turn-arounds and planting strips and unimproved property in absentee ownership (see cluster plans).

Maintenance and operation of community sewerage and water systems.

Performance of services such as street repair, snow removal, and garbage collection until taken over by the municipality.

Representation of the owners' needs or opinions to the public authorities.

Development of community programs—social, cultural, or recreational.

NEW APPROACHES

Although the standard subdivision technique of today is a vast improvement over the monotonous grid-iron plots of the past, many planners feel that it still leaves much to be desired. They believe that it is possible to preserve the beauty of the natural land, to relate the houses better to each other and to the site and provide more open space, all at less cost than in today's practice.

An early example of this type of thinking is the Radburn plan (1929) in which the houses are grouped on small lots around culs-de-sac which penetrate the periphery

Existing street patterns

Good

Poor

When diagonal streets cannot be avoided

When existing streets form acute-angled intersections

When future street extensions are not required in corners of the property

Economy of
utilities

EXPLANATION

1. Excess underground utilities at end of block required.
2. No underground utilities at end of block.
3. Rear overhead utility easement.
4. Street overhead utilities.
5. Increased corner lot width.
6. Corner lots too narrow.
7. Good use of butt lot.
8. Butt lots require extra utilities with bad view down rear lot line.
9. Good lotting at street intersection.
10. Required underground utilities.

Courtesy Federal Housing Administration

of huge superblocks. The center of each superblock is a park on which all houses face. Pedestrian walks lead through the parks to schools, shopping, and transportation.

A more recent example of the same general approach is the cluster scheme shown in comparison with more conventional plans in Fig. 16. This plan reduces the cost of streets and utilities by half and leaves approximately half the total site for recreation. Every house abuts on a park or open land. Although normal suburban densities are maintained, the rural character of the land is preserved, there is less monotony in the appearance of the development, and better living qualities are provided, all at less cost than in conventional subdivisions. The common land must be maintained by a neighborhood association; it could be treated as a park or playground or it could be left in its natural state, especially if wooded, rocky, or otherwise attractive in appearance.

Unfortunately, neither the Radburn plan nor the cluster plan are permitted under most existing zoning ordinances and subdivision regulations. The rigidity of these regulations has been a serious handicap to any significant improvement in subdivision site planning. Further examples of this are illustrated in Fig. 17.

Residential
SITE PLANNING

Fig. 15. Parking areas for rental housing
Courtesy National Association of Home Builders

Fig. 16. Cluster scheme compared with conventional subdivision plans for the same site

All schemes have 94 lots. Lot size in cluster scheme is $\frac{1}{3}$ smaller than in conventional plans. Linear feet of streets and utilities in cluster plan is half that of the other plans. Cluster plan leaves approximately half of total site as open space. All houses abut on open space. (Stephen Sussna Associates, Designer. Courtesy Urban Land Institute.)

Residential

SITE PLANNING

The approved subdivision represents current development practice fully conforming to most zoning and subdivision ordinances. The subdivision plan (1) provides for 280 families (9.3 families per acre) in twin houses with basement garages. Curving streets are an improvement over the traditional gridiron pattern, but their repetition in numerous subdivisions has created a new monotony. The curving streets only partially obscure another monotony: the uniformly spaced houses. Access from both boundary highways invites through traffic. The similarity of lots, and lack of integrated communal areas, is only too apparent in detail (2). Plan of the typical house, three stories above street level, basement garage, is shown in (3).

Scheme A houses the same 280 families. The new street pattern excludes through traffic. The twin house is replaced by groups of houses of varying lengths and varying setbacks. No houses face on the busy boundary highways. With garages out of the basements, the houses need be only two stories above street level, thus eliminating artificial terraces and giving direct access to private gardens which are supplemented by tot lots, sitting areas, a small common, and parklike walks.

Fig. 17. Existing regulations may block improvements in subdivision design
From a study by the Philadelphia Housing Association, 1961.

Scheme B also provides for 280 families. Groups of houses face on courts instead of streets. Parking compounds in each court justify elimination of individual garages. As in *Scheme A*, tot lots, sitting areas, common areas and interior walks are provided in addition to private yards and gardens.

Scheme C shows the number of families reduced from 280 to 165 (5.7 per acre). Groups of twelve houses front on pedestrian courts. Access for cars and service vehicles is by looping driveways behind the houses. Visitors park in the compounds at the entrances to the courts. The low density results in even more generous open space than in *Schemes A* and *B*. Through traffic is excluded from the subdivision and, again, the boundary streets are not used for lot frontages.

Schemes A, B, and C fulfill the basic objectives of zoning: promotion of health and general welfare, provision of adequate light and air, and prevention of overcrowding of the land, of undue congestion. Yet, under most existing zoning ordinances *Schemes A, B, and C* cannot be built.

GENERAL REQUIREMENTS

Typically, the nursery class consists of 15 to 20 children, 1 teacher, and 1 assistant teacher. For this we recommend a minimum of 700 sq ft of instructional space excluding observation and office area. The optimal area would be 1,000 sq ft. This discussion focuses on a classroom for a single group, but, through creative planning, a nursery classroom of unconventional shape could be designed to accommodate two or three nursery class groups (30 to 60 children).

The classroom environment should foster a climate conducive to the educational objectives of the program. For example, children may have difficulty learning to be relatively quiet and attentive in a noisy environment or sitting in uncomfortable positions. Children may be inhibited in the development of self-reliance if the environment forces the teacher to supervise their every move.

The classroom's arrangement should contribute to the child's concepts of order and space. A perceptually clear and distinct room environment, achieved through uncluttered equipment and furniture arranged in an orderly fashion, helps the child focus his attention on the curriculum instead of distracting him with irrelevant stimuli. Daily contact with an uncluttered, structurally simple environment helps to teach time and space organization. Tidiness is a secondary benefit.

The nursery classroom should consist of a series of well-defined, interrelated areas, including a general area for group activities, a reading corner, a doll corner and housekeeping area, an area for blocks and another for manipulative toys, an art corner, and storage cubicles where the children hang their hats and coats and keep their possessions. Rest rooms and storage areas are also essential. A separate tutoring booth is desirable because it provides a special environment for individualization of instruction and for teacher-child interaction. (See Fig. 1.)

The smaller the total space available, the more careful must be the selection of what to include. Regardless of the room's size, it is imperative to maintain neatness, orderliness, and general attractiveness, with adequate space around objects and areas in the room. Empty space around objects is necessary: when a child's attention is directed to a group of rubber animals, for example, he must be able to see them unobscured by adjacent objects.

Teachers who have taught only in square or rectangular rooms seem to prefer large, open spaces which make visual supervision of an entire room possible from any vantage point. If more than one adult is in the room at all times, there is less need for such supervision. Furthermore, a rectangle of 1,000 sq ft has some disadvantages. Such a room appears extremely large to small children. It makes it difficult to create corners for reading and other quiet activities.

And it almost eliminates the possibility for a child to be alone with an adult.

A rectangular room is by no means ideal, and, if it is necessary to use one, it should be broken down into specific areas with freestanding dividers and cabinets.

Acoustical control is a fundamental concern in designing nursery schoolrooms. Children's voices are high-pitched, and many activities, both noisy and quiet, take place at the same time. Because disadvantaged children need special help in discriminating sounds, the classroom itself should be as free as possible of acoustical distractions.

A carpeted floor is recommended for acoustic purposes and for its other advantages. It is attractive, is easy to maintain, and provides a warm, comfortable surface on which the children work and play. Using carpets of different colors and textures helps to define different areas of the school. Only the art corner, because it is cleaned with water, requires a hard surface.

The size of the children must be kept in mind in planning display areas. Any display higher than 4 ft-6 in. is beyond the small child's usual range of awareness. Most children can select their own books or puzzles if the top shelves are not higher than 3 ft-6 in.

In planning the number and placement of windows, consideration ought to be given to the view outside the window. Where the school setting affords a pleasant, changing view, windows might be included as integral parts of the classroom. Windows should be low enough for the children to see through. When windows would expose only the monotony of a brick wall, the space traditionally given them might better be used as space for classroom displays.

In the second case, skylights and translucent wall materials are effective ways of providing natural light in the classroom without losing valuable wall space.

THE GENERAL AREA FOR GROUP ACTIVITIES

As already mentioned, a nursery schoolroom comprises a general area and several specific corners or alcoves for special activities. The general area should be an open space of at least 150 sq ft for group activities like singing, dancing, and listening to a story.

It is frequently advisable to seat all the children and adults around tables. The same tables can be used in the art area, the reading area, or the manipulative toy area as long as they can be pulled together easily in the larger area for group activities.

Music activities can take place in the general area. Carts are needed here for a record player and a tape recorder, and closed shelving for items such as rhythm instruments, autoharp, guitar, and drums.

The general area should have a central place containing shelves for displays that change every few days. The display shelf should be about 4 ft long, with a bulletin board above it and one shelf below. The shelf should be 15 to 20 in. high to accommodate small animal cages, canned vegetables, and the like. A sliding bulletin board over a fixed one would allow various displays to be exposed or covered at the teacher's will.

Where there is no opportunity to grow things out of doors, a planter for raising flowers, plants, or vegetables is essential. Other useful

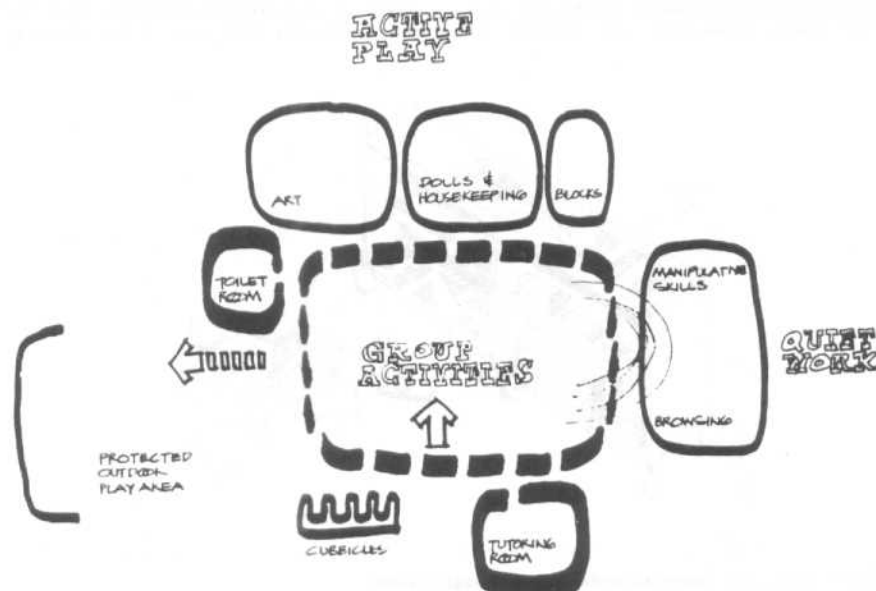

Fig. 1

NURSERY SCHOOLS

equipment in the general area would include a hot plate and a refrigerator.

THE BLOCK AREA

Blocks provide a wide variety of learning opportunities. These opportunities include development of self-expression, muscular coordination, and cognitive skills. Building structures that are shared with and admired by peers and teachers help the child view himself positively.

The block area could be a little alcove (24 to 30 sq ft) outside of the major traffic area but opening onto the general area. This arrangement creates a protected space where children can build something that won't be inadvertently knocked down by children engaged in other activities, and it also provides the necessary space for several children to play with the blocks simultaneously.

Unpainted, rectangular unit blocks, uniform in height and width but varying in length, are used, along with blocks of various shapes—triangular, curved, and so on. Blocks of the same shape and length are stored in separate stacks with enough space between the stacks to make them easy to arrange. The lengths of the blocks, which vary, are exposed rather than the ends, which do not vary. Silhouettes painted on the shelves help the children to find and replace the blocks by themselves. (See Fig. 2.)

At the beginning of the year, 16 lin ft of shelving, at least 11 in. deep and having at least 10 in. between shelves, is adequate. As the school year progresses, more blocks are added. These may be shelved in movable cabinets that can be rolled into the classroom when needed, and then left in the room. If the storage shelves for the blocks are no higher than 2 ft, small items, such as toy trains, cars, planes, boats, animals, and figures of people, can be displayed on cabinet tops, their places marked by painted silhouettes.

MANIPULATIVE TOY AREA

Play with manipulative toys complements and enhances some of what children learn when playing with the blocks. By playing with colored pegs and pegboards, lockboards, small unit blocks, Cuisenaire rods, puzzles, felt

boards and geometric forms, nuts and bolts, nesting cups, and similar toys, children can learn colors and develop perceptions of size and form as well as of mathematical concepts.

The manipulative toy area is basically a quiet area where children work individually. It can be by itself or part of the area for reading and listening. Two or three two-shelf, open cabinets are sufficient to display the manipulative toys. Puzzles are best displayed on sloping shelves so the children can see them all as they select the ones they want to use. A cabinet above the manipulative toy area is a good place to store toys and puzzles not currently in use; the number and complexity of toys and puzzles are increased as the year progresses. A table that can accommodate at least four or five children should be located near the display cabinets. (See Fig. 3.)

READING AND LISTENING AREA

Children will come, individually or together, to the reading and listening area to look at books, to be read to by the assistant or the teacher, or to listen to a story on a tape recorder. These activities are probably more important for disadvantaged children than for children from more advantaged homes. The typical home of the disadvantaged child might not have available sufficient kinds and quantities of children's reading material, and there will probably not be a quiet, uncrowded place for the child to learn to listen.

The reading and listening area should be a quiet place well away from the block area, art area, and housekeeping corner. The space should be well defined either by walls and dividers, by cabinets, or by a difference in ceiling height, floor elevation, lighting, or color and texture of floor or walls. This area could be elevated two or three steps above the general area, an arrangement that would convey a feeling of its being special, separate, and cozy. If elevated, it can also serve as a platform for dramatic activity, and the children can sit on the steps when they are being read to.

The reading corner requires sufficient display-shelf space for showing the front cover of each of 20 to 25 books. The highest shelf should be no more than 3 ft-6 in. from the floor—preferably 3 ft only. If the shelving

Fig. 3 Sloping shelves for display of books and puzzles.

cannot be adjusted, there should be at least 14 in. between the two shelves. Thirty-two lin ft of shelving provides enough space for books.

There should be a place to display one book and related small objects and pictures. An adjacent bulletin board adds to the display.

In addition to the bookshelves and display area, it is highly desirable to have a low shelf or table, available to as many as six children at a time, on which to place specialized learning equipment such as a cartridge tape recorder.

DOLL AND HOUSEKEEPING AREA

The doll and housekeeping area requires a dress-up area, dolls and necessary accessories, cooking and eating utensils, and general housekeeping equipment. Some authorities feel that as the year progresses, the housekeeping area should be increased, while other authorities would gradually eliminate the area completely.

The doll and housekeeping area is the area most children will first turn to when they come to nursery school. It is a link to the home, and at the same time it provides the opportunity for expanding the child's concept of what a home can be. Some disadvantaged children are unfamiliar with many things that teachers assume are standard equipment or practices in any home. Some families, for instance, may not have organized meals when everyone sits down together to eat. Instead, family members eat at different times, and not necessarily at a table.

The housekeeping area might present a major problem—it can be so attractive to children that some of them will want to spend most of their time there. It is for this reason that some authorities would begin the year with a complete housekeeping corner and gradually eliminate it. Presumably, as the area is decreased, children will either move into other areas of the room, or, if they remain in the housekeeping area, become more creative in their play.

The dress-up area is usually of great interest to the children. It should include a child-size chest of drawers and either hatboxes or open shelves for dress-up clothing (shoes, hats, jewelry, material suitable for belts, trains, capes, veils), a full-length mirror, and a tele-

Fig. 2 Block carts. Colored silhouettes indicate storage locations.

phone connected to another telephone elsewhere in the room. One telephone should be placed so that the child can look into the mirror while talking. The second telephone need not be fully enclosed, but neither should the child be able to see or hear (except through the receiver) the one to whom he is talking.

Dolls and the necessary accessories also provide important opportunities for learning. Through their own explorations and through interactions with the teacher, children learn textures, the names and functions of objects, colors, manipulative skills, and the routines of their own daily living—dressing, eating, going to bed, and the like.

The cooking area requires a child's stove and refrigerator, cooking utensils, other equipment such as plastic fruits and vegetables, and a container for juice or milk. There could also be a sink, open shelves, and a pegboard. The shelves would hold table flatware as well as many of the other utensils found in the average kitchen. There should be enough space between objects to present an orderly appearance, and the pegboard should have silhouettes of each object to encourage the children to return each item to its place. A child-size table and chairs complete the cooking area.

Finally, the housekeeping area should include places for a child-size ironing board, iron, clotheslines, mop, dustpan, and broom.

ART AREA

In the art area, a few children at a time paint pictures; make finger paintings, collages, and mobiles; or play with clay, modeling compound, paste, crayons, marking pens, and an assortment of other material such as soda straws and pipe cleaners.

The art area should be away from heavy room traffic and should have limited access. It requires a sink for washing hands and cleaning paintbrushes and sponges. Ideally,

there would be two sinks—one at the appropriate height for the teacher and a lower one for the children. If only one can be provided, it should be at the appropriate height for the children's use.

Two kinds of storage space in the art area are desirable.

In the first, sheets of newsprint (usually 18 by 24 in.) and of colored construction paper should be stored within easy reach of the children. Construction paper should be arranged so that a child can take one color without disturbing the other stacks. The teacher might also store crayons, marking pens, and paintbrushes here.

The second storage space, for such things as scissors and paints, should be closed and out of the reach of the children. The storage cabinets can also serve as room dividers.

The art area should have space enough for two or more children to paint at one time. A regular easel with room for painting on either side is satisfactory; or three or four easels side by side could be provided by sloping a long piece of plywood or masonite out from a wall or room divider. The latter arrangement has the virtue of providing more work area in less space, and it allows the young painters to admire each other's work. Easels should be easy to clean, and the tray that holds the paints and brushes should be removable for cleaning.

A table is important in this area. It should be large enough to accommodate four children playing with clay, using finger paints, or pasting collages. The table should be about 18 in. high and have a work area of 15 sq ft or more.

Art activities provide a feeling of accomplishment and recognition that helps a child feel positive about himself. One of the ways to reinforce this is to display the child's paintings, but to display all the children's paintings simultaneously destroys the clarity and attractiveness of the room. If, somewhere in the room, at child's eye level, a display space is provided for five or six 18- by 24-in. pictures,

and if the pictures are frequently changed, each child can see his work exhibited many times during a year. It is not necessary to display all the children's art work at once.

Provisions should be made for hanging paintings to dry. There should be enough space for at least 12 paintings to dry at one time.

TUTORING BOOTH

It is essential that an enclosed space be provided for teaching one child at a time. The enclosed space, or tutoring booth, enables a child to be free of distractions while working with a teacher or with specialized teaching

Fig. 4. Individual cubicles.

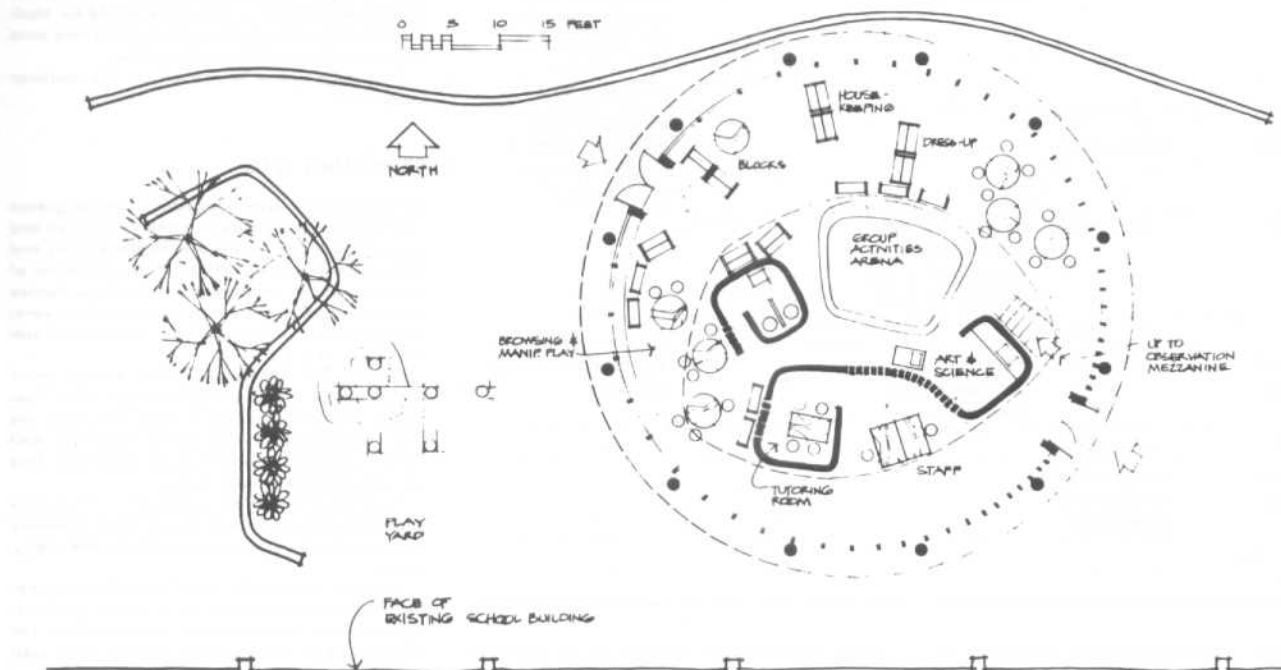

Fig. 5 Proposed nursery.

NURSERY SCHOOLS

A Summary of Space Requirements

Activity	Space, sq ft		Storage	Display	Other
	Min.	Opt.			
General area	150	200	Carts, closed shelves for music equipment	2 centrally located shelves 4 ft long, 15-20 in. apart; bulletin board	Planter; hot plate and refrigerator (or in additional storage, below); tables (can be tables from other areas if easily movable)
Block alcove	50	75	Shelving 16 ft long, 11 in. deep, at least 10 in. high, plus supplementary shelving in movable cabinets to be added through school year		
	(Can be 24-30 if play can expand to general area)				
Manipulative toy area	100	150	2 or 3 two-shelf open cabinets; sloping shelves for puzzles; cabinet for toys not in use	Open and sloping shelves (see Storage, left)	Table for 4-5 children; should be quiet area
Reading and listening area	(Combined with manipulative toy area)		Closed case for duplicate books out of children's reach	32 ft of low, open shelving for 20-25 books showing front covers; shelf and bulletin board for special exhibits	Table or low shelf for tape recorder, accommodating up to 6 children
Doll and house-keeping area	100	150	Drawers and open shelving for dress-up clothes; dolls; open shelves and peg-board in cooking area		Full-length mirror; 2 telephones; sink (can be shared with art); table and chairs in cooking area
Art area	100	150	Open shelves for newsprint and construction paper; shelves accessible only to teacher for paints, scissors	Sufficient to hang 6 18 x 24 inch paintings	Easels; sinks (one for children—may be shared with housekeeping area; one for teachers—may be in additional storage area); table 18 in. high with area of 15 sq ft; space for paintings to dry
Tutoring booth(s)	45	50			Enclosed for privacy; if only one teacher is available, partitions should be glass
	(each)	(each)			
Cubicles	60	90	For pupils' clothes and other belongings; should be 4 1/2 ft high, 1 ft wide, 1 ft deep		
Toilets	40	50			
Additional storage	30	100	Refrigerator, hot plate (see General Area, above)		May serve as teacher's utility area
Total	675	1015			
Observation space	Can be combined with additional storage area				
Outdoor play area					

equipment. This space might also serve as a testing area or simply as a place where a child can be alone with an adult. These activities are important and such a space should be provided even if, as a consequence, the size of the main room is reduced.

In some instances, it might be feasible to

create a room within a room by enclosing an area large enough to accommodate a small group of five or six who could work away from the distractions of the rest of the class. If only one teacher is to be present in the class, the walls should be transparent to allow the teacher visual control.

INDIVIDUAL CUBICLES FOR STORAGE

Each child should have a place of his own in which to hang his hat and coat, set his rubbers or overshoes, and store things that belong to him. These cubicles, or cubbies, should be about 1 ft deep, 1 ft wide, and 4 ft-6 in. high. The child should be able to sit down in or near his cubicle to put on his shoes. (See Fig. 4.)

TOILETS

Where rest rooms for the children are not adjacent to the classroom, inordinate time is wasted in moving children to and from the rest room. If rest rooms are integral parts of the classroom, children can use them independently and develop self-reliance.

The theory that the fixtures should resemble those in the children's homes has merit, but the overriding considerations are convenience and utility. The wash basin and toilets should be appropriately sized for children.

STORAGE SPACE

To ensure an orderly and neat room and reduce the number of stimuli present at any one time, storage space outside the classroom is important. It can also serve as a utility area for the teacher and should contain a large sink for preparation of paints and for cleaning up.

If a sink is provided here for the teacher, only one sink, placed between the art and housekeeping areas, is necessary in the classroom. The hot plate used in the classroom and a refrigerator for keeping milk and juice belong in the outside storage room if possible.

OUTDOOR PLAY AREA

The outdoor play area could include a planting area, a sandbox, an open area for play with balls, hoops, inner tubes, boxes, and boards. Ideally, some part of this area would be sheltered to allow the children to spend some time outdoors during inclement weather.

A storage space is needed for the outdoor equipment.

OBSERVATION SPACE

An observation area is desirable for programs that encourage parents to observe classes and to become more involved with the school and the education of the child. A combination of one-way glass, microphones, and earphones will ensure separation of pupils and observers; one-way glass with a louvered panel would suffice. (See Fig. 5.)

Ideally, the observation area should be 1 or 2 ft higher than the regular classroom. That would give the observer a good view over the low room dividers and would leave the wall space below the observation windows free for cabinet and display space.

An alternative to an observation room is a closed-circuit television setup that provides viewing at a location removed from the classroom.

Acoustical control in the classroom is essential. Without this control it is virtually impossible to hear or to transmit the speech of the children. Sound-absorbing ceiling and wall tile, draperies, and carpet all merit consideration for inclusion in the classroom.

The observation area should open directly on the corridor or outside, allowing observers to come and go without interfering with the children and the teachers.

Figure 1 shows one suggested organization for a children's center to accommodate approximately 60 children.

Children's playrooms, one for each age group, shall be provided, as a rule. Playrooms shall be self-contained, without folding partitions. Minimum area of one room (for the youngest children) shall be 550 sq ft; the other rooms shall be at least 750 sq ft each. The minimum area per child is 30 sq ft. Square rooms are preferred. Southern or southeastern exposure is desirable; northern exposure alone is not acceptable.

The rooms shall be protected from public view, either by the playground or by landscaping. Ceilings shall be 10 ft high, and shall have acoustical treatment.

Services for Children's Playrooms

Toilets A toilet for each playroom opening from the room, near the playground door. At least two lavatories and two water closets shall be provided in each toilet room. Water closets shall be 10 in high in toilet for the youngest children, standard height in the other toilets. Lavatories shall be 21 in from floor with strainer in drain.

Play Area Each playroom shall have direct access to an outdoor play area, divided by fencing into two separate unequal sections (the smaller for the youngest group) with gates for access. Minimum area shall be 4,500 sq ft, minimum width, 50 ft. The play area shall be partly shaded by a canopy or overhang from the building.

Toy storage shelter for outdoor toys, with convenient access from both sections of the play area.

Other arrangements are shown in Figs. 2 and 3.

INTRODUCTION

School building has passed through the years and styles of building to finally free itself of the constraints of building in some certain way. The response now is to the *real* needs and reasons for education, to *change* and *flexibility* and an *awareness* that the buildings are simply and primarily for children to learn in, teachers to teach and learn in, and staff and parents to "lend a hand" in.

The log cabin and the one-room little red schoolhouse are a far cry from the prideful community institutions of the early 1900s. But are they indeed so far from ungraded schools, modular scheduling, turf space, magnet schools, and a host of self-initiative plans?

The technological and communication races pace and outpace people's performance and their acquaintance and acceptance of ever-new ideas and increasing information. Learning must be accelerated, horizons broadened, and differences narrowed between urban and rural communities. Still, some communities are doing better and have more innovative programs, more responsive staffs, and more total determination. The facilities alone can only do part of the job.

Education is life and people doing things. The school is both a kind of shelter and a kind of stage. It brings together children and adults on the day-to-day business of contending, learning, working hard, having fun, and growing up. It focuses attention and is a focus of attention. It is its own community and a critical part of the total community.

The process of planning a school which will respond to the real needs of learning, teaching philosophies and community objectives and which will really meet the basic uncommon denominator, its children, is complex and challenging. It demands a nice balance of experience, wisdom, professional skills, and uncommon sense on the part of all involved.

Only part of the objective should be a well-conceived, efficient, practical, soundly constructed, quality building. It must, too, be changeable and compatible with its children and its own community of users. Buildings do not die of old age, but of design obsolescence or overindulgence. The architect is and should be regularly challenged to conceive ways in which school facilities may be designed not only to be a practical, efficient response to the needs of today's teaching technologies, but also to anticipate the inevitable changes by which learning will become an entirely different experience.

Environment

The architect's efforts must be put into the creation of a school which actively and attractively suits the functions of the education it serves and which not only *accommodates* but also *contributes* a very special environment

for learning. "Environment for learning" connotes a broad range of special qualities, evidenced by many characteristics of a building's design. The physical aspects of environment—those relating to the bodily senses of temperature, vision, and hearing—may be relatively well controlled by known engineering methods. Those environmental qualities which affect emotions and behavior are far more difficult to accomplish through building design since they are not subject to established formulas or systems. Human scale, hominess, warmth, excitement, and repose are recognizable attributes of a building which engenders real responses from its occupants. The environment of a school should be one which actively stimulates the development of human beings—socially, intellectually, physically, and emotionally. Creating an environment, and not just a space, should not be a bonus, but rather is a minimum essential.

Program Involvement

The architect properly seeks to provide services early in the planning stages prior to the actual design and construction of school facilities. This is so that he can contribute with the best of his experience and technical knowledge in the processes of site selection, preparation for bond issue referenda, time scheduling, programming, and budgeting. During the early planning stages the architect may gain insight into the philosophical attitudes of the school board and administrators and the nature of the community or neighborhood for which new or added school facilities are needed. It is during this time that ideas can be exchanged.

The architect should know the community he serves by considering as parts of his total responsibility the following:

1. The nature of the total community setting and its people
2. The character of the neighborhood surrounding the site, e.g., high-density multi-family, single family, mixed uses, obsolete, declining, stable, or growing, and the presence of significant environmental influences such as air or noise pollution
3. The projected rate of growth, if the community is developing, as an indicator of phased construction of the school

Teaching and learning programs must be formulated and facilities must be planned in response to the anticipated educational, cultural, and social needs not only of the school-age members of the community but of the adult group as well. A predominantly vocational-technical orientation is generally indicated for a school in a largely industrial community. In an area where a high percentage of students go on to college, the school's curriculum must include preparatory liberal arts subjects. The intensified academic programs necessary today are tempting communities to extend the typical

nine-month school year and to lengthen the school day. Summer sessions are becoming conventional both for makeup work and for programs of acceleration and enrichment. Some communities have implemented full twelve-month use of their facilities, some on a basis of 45 days of school, 15 days of vacation. Extracurricular activities, most of which are offshoots of formal scholastic work, such as foreign language and science clubs, school publications, special music groups and dramatic organizations, are carried over into after-school hours and evenings.

In addition to housing the regular school programs, the building will probably also accommodate adult evening classes, PTA meetings, public lectures, concerts, and similar educational-cultural events. Add to these a variety of civic functions, such as town meetings and park recreation projects, and we have the "town hall" school busily serving as its community's educational and cultural center practically around the clock and all year long.

All these considerations influence the broad strokes of decision making for the form of the school. Beyond these are the "educational specifications," which spell out the details of the school program in terms of optimum size of enrollment; teaching loads; scheduling (modular or conventional); organization of the instructional program ("school within a school," "house plan"); learning methods (team teaching, individualized instruction, independent study); and all the mechanical, electronic, and audio-visual aids to the learning process, in addition to the library as "instructional materials center." Additionally, physical education, competitive athletics, recreation, cultural, and social needs must be accounted for.

Space, Quality, Cost

These functions together make up the plan-dictating, form-generating influences that the school board, administration, citizens committees, and architect must consider in establishing the priorities of space, quality, and cost which will govern the design and construction of the new facilities. It is axiomatic that these factors shall be placed in balance, if the results are not somehow to be frustrated. In applying the space \times quality = cost formula, only two factors can be fixed by the client. The architect must be allowed to vary the third; i.e., if space and cost are rigid requirements, the only variable then is *quality* of materials and construction. Obviously, inefficient planning can rob the administration of space urgently needed to carry out the desired programs. Unless appropriate materials, equipment, and finishes are used, the board of education will be forever burdened by excessive maintenance and operation costs; and if, through lack of discipline over these factors of space and quality, the project cost exceeds the funds that have been voted, the community will, assuredly, be most

ELEMENTARY AND SECONDARY SCHOOLS

General

articulate in voicing its displeasure. In school design the architect must reject wishful thinking, whether it be his own or that of his client.

It is rarely understood by voters that the overwhelming cost of the school system is for teachers' salaries and related educational expense. Even if schools cost nothing to build, the effect on a citizen's tax bill for education would be relatively trivial. Depending on whether a school district is well established with existing buildings, or newly created with buildings yet to be built, the budget for the building and financing of the physical plant over its lifetime varies from 5 to 15 percent of the cost of educating a child. Of this cost approximately half is chargeable to financing—the interest paid on bonds. Cheap and inadequate educational facilities save little initially and, for the long run, are indeed poor investments and are permanent handicaps to the learning/teaching process. Therefore, those who defend high quality do so on sound economic ground. The benefits of education require no defense.

All of what goes into a school, what must be considered is outlined in the following pages. The task is complex, the options are many, involving the input of people, money, effort, patience, and finally providing a gratifying reward when the job's been done well. Schools can be and should be fun to be in, for everyone.

By STANTON LEGGETT, Educational Consultant

EDUCATIONAL CONSULTING

Purpose

In order to state the needs of an educational institution and to relate a facility more closely to the educational program, communities, schools, and colleges increasingly use an educational consultant as a primary member of the planning team. A school planning project, whether for a new building or for a master plan for an institution, should be used not only to construct a good facility but to provide a setting for effective restudy of educational programs and to allow a time for examining new perspectives of learning. With close personal contact between a consultant with wide experience and a faculty that must search its collective soul before the concrete is poured, a prime time is created for real in-service education. The operative word is *real*.

Procedure

As in education, the name of the game is *process*. While the assessable outcomes of a facility planning procedure are most important, dollars for consulting services can be used twice: once for the building product and once for the process of involving many people in planning and decision making.

Greatest advantage can come by designating a planning cadre who will ultimately take over operation of the new institution. Alternatively, a group of potential operators of the educational system could be involved. Further options include general participation by parallel staff members from other schools or colleges.

When groups to participate and to be involved are identified, one useful device is to select a steering committee. Hopefully, a steering committee will include a cross section of the people who will be involved, people with optimistic but not necessarily similar views.

Also it should be composed so that it will give credibility to the work of the committee. The steering committee should steer. The consultant should become working staff for the committee.

The planning process should involve as many people as possible, and the consultant must be responsive to the direction of the educational institution. The consultant is a temporary employee of the school system. The school system should induct the consultant into the problem, providing wide opportunities for him to get to know where the institution is going, what the educational aspirations of the community are, and how the new facility should help the system achieve its goals.

While the process of induction is going on, where many people tell the consultant about the problem or the purpose, the consultant is making his contribution. This is, essentially, to widen the spectrum of choices or options that are considered by those involved in the planning process. Viewing and discussing ways to meet objectives should go on for some time—long enough so that all the participants feel that they have really explored and participated, but not so long that frustration sets in.

The consultant somewhere along in the process takes on another role—organizer of chaos. It is his task, as temporary staff to a decision-making organization, to develop a first document which states the problems and offers a set of alternatives to consider in decision making about general directions. Such a report should be made widely available to the staff or the involved group for review, critique, revision, deletion, and addition. A program of needs for a building or the base for a master plan evolves from the basic study and evaluation of options, leading through successive revisions to descriptions of spaces in terms of numbers, sizes, and characteristics.

EDUCATIONAL SPECIFICATIONS

The development of a formal document of educational specifications for new educational facilities is now accepted practice in approaching the construction of educational projects of any consequence. The document is designed to formalize and organize the needs of the users of the school so that the design can be developed to house these needs.

Outline of Educational Program Document

1. *Educational concept of the facility.* A brief statement should be made of the educational goals and purposes to be accommodated by the facility. Discussion of the educational philosophy to be followed is necessary. Make a general description of the facility and its basic elements. Draw up a statement of design objectives.
2. *Activity program and space requirements.* Make a general description of the assumed academic curriculum and other activities at the facility. Make a general description of types of space required and teaching methods to be used. Data are to be summarized in four charts:
 - a. Activity program chart
 - b. Space requirements and utilization chart
 - c. Area summary chart
 - d. Environmental conditions chart
3. *Detailed area and equipment requirements.* For each activity area, write a narrative outline of how the various spaces in it will be used, their relationship to each other, and their relationship to other parts of the facility. For each activity area, provide a detailed list of all spaces, giving areas and equipment for each. Data are to

be summarized on two standard forms:

- a. Space list
- b. Equipment list

Flexibility and Change

All schools must be as flexible as possible in terms of space. The spaces in them must be easily adaptable to new uses and arrangements in the future. The types and division of spaces given in the program should not imply structures that cannot be easily modified for changing needs in the future.

The operative idea in the traditional view of educational specifications is *specific*. The approach assumes that a school or college can be "frozen" at a point and fixed there with all the elements held constant while the architect designs an environment. Change an element and the design process must start over again, for the "program" has changed.

It is not easy to describe a viable alternative to this process, because the human mind cannot deal realistically with an infinite number of variables at the same time and come up with a definite and specific answer, be it a building or educational program. When we have fully learned to supplement the mind of man with the memory of a computer, we will have better success in dealing with the dynamics of a school or college and the creative environment.

The school is a planning process, an envelope for change. The objective is to develop a building that provides the environment for growth and change, not to pin education down.

Process

The educational specifications for a school that emphasizes *process* are as general a set of specifications as it is possible to agree upon while, at the same time, securing an appropriate building. To as large a degree as possible, the arrangement of the space, the staffing of the school, and the deployment of the resources should be left up to the people who will use the school. The educational specifications will be the beginning of the planning process which will continue through the life of the school. The specifications may describe the first of any environmental settings for learning experience.

Part of the design process should be to create models of teaching spaces so that the planning group for the school (teachers, students, and parents) could make value judgments about the use of space and try them out. These models serve as bases for simulations. People learn a great deal from simulations, for in this manner the consequences of actions or decisions are seen graphically and realistically.

The educational specifications can help by being constructed on a modular basis and by including examples of the options that exist within the more generalized requirements. The architects can contribute much by graphically representing the wide variety of ways people can organize themselves within the pliable, yet not anonymous, environment the architects have created for them.

The educational consultant is not an architect, nor vice versa. As the planning process moves from words toward lines, the consultant's role changes. The planning organization, of which he is a part, responds to the designs of the architect. For this is a team process. A good team uses all the qualities of the participants as fully as possible and shifts roles unobtrusively, but responsibly.

ARCHITECTURAL PROGRAMMING

Architectural programming is the specific defining and analysis of physical needs. It is

ELEMENTARY AND SECONDARY SCHOOLS

General

also the defining and analysis of constraints, like budget, code, site, and time schedules imposed upon those needs. Architectural programming is not educational programming, but follows and evolves from it.

Objectives

The prime objective is to define the problem: to clearly state the physical spaces required, the uses of these spaces, the functional relationship between them, and the occupancy and equipment needs of each space, all in a format understood and approved by the client.

Procedure

The first step is to determine who will participate in the planning process to follow. Included should be the owner, the educational consultants if involved, the architect, and any others who will have a direct bearing on the end result. These representatives should have the authority to make the day-to-day decisions on the formation of the program. In the case of a larger project, such as an urban high school, additional consultants may be required. They should be brought into the programming process as soon as possible so that the end result benefits best from their expertise when their recommendations of basic philosophy and policy are incorporated.

Secondly, a time schedule should be set with a final target date. It is essential. It should go beyond the programming phase and relate to an overall schedule including completion of construction and occupancy. Adherence to a schedule from the very outset imposes a constructive discipline and a healthy sense of urgency encouraging interaction among the participants. Modification or change of a schedule can then be appraised in light of the overall effect on time of occupancy. The time schedule clearly defines those points in time when approvals and reviews are required or desirable.

Thirdly, there should be a sequence and methodology: establishing the aims, organizing and collecting the facts, seeking out meaningful inherent concepts, and determining the needs (not wants) consistent with realistic constraint. The needs should then be stated in terms of interior and exterior spaces, site, budget, and time schedule.

Fourth, there should be a format and technique that graphically portray the parts. A picture is worth a pile of words. The technique should be consistently followed so that the continuing experiences can be added and their implications made clearly visible.

Finally, meetings should be scheduled in a "neutral" location. Meetings do not have to take place in the school building. In fact, there may be fewer interruptions elsewhere, and new ideas might be generated best in new surroundings where inhibitions are left behind.

Content

A complete architectural program should contain the following information:

1. *Statement of use by owner.* Adult education, community concerts, and other similar activities have a direct bearing on the planning of schools. In some urban schools, for example, specialized instruction in one school serving students throughout the city might require much more ample access into the site, as well as extraordinary circulations and toilet requirements. The complete, intended use of the facility should be made clear, as well as its place in a total educational system since that too may affect its future use.

2. *Basic concepts of teaching/administration.* What the approach to teaching and admin-

istering will be has critical influence on space needs, size, and building type. Team teaching and differentiated staffing would call for large open space and a variety of space sizes. Modular scheduling in a variety of class time periods dramatically affects space utilization. Will it be an open campus with students free to leave the building during "free" periods, or must the entire student body be housed in the building's spaces during all periods? Will there be study halls or free library or lounge access? Will the school be divided into subschools? Particularly in larger schools and school systems the matter of food service can influence decisions on plan organization and program organization. Counseling arrangements can be related to the administration offices or faculty-department grouping. The whole concern of administrative centralization versus decentralization can pull a plan one way or another.

3. *Spaces to be provided.* All details of the space requirements should be recorded, their size, how many of each size, the number of occupants in each space, the number of teaching stations, the equipment demands, their relationship and functions, and other special comments should be noted. With even a minimal experience in school design, a format can be developed to cover all basic types of school facilities as a checklist in developing a particular program. Through experience, certain guidelines and "rules of thumb" have been developed for school planning. Unit areas have gradually increased over the years, with the trend toward more individualized instruction, more specialized and diverse course offerings, and greater reliance on special equipment. Typical basis for calculation includes number of students per teaching station, area per student by types of space, gross square feet per student, and cost per student.

4. *Graphic representation.* It is most useful and makes clear to everyone relative sizes and priorities for consideration if the individual program parts and their numbers are graphically illustrated. All interior spaces and exterior spaces like playfields and parking lots should be shown to give a good overall picture of what the total space needs are in relation to land available and what various parts of the program physically represent in area relation to others. Some initial bulk areas may be additionally included to represent circulation, storage, and service requirements, and to indicate the relationship between net and gross areas.

5. *Limits/constraints.* It is also a prudent reminder to carefully note the various constraints on the programming process, like budget, time schedule, codes, insurance provisions and ratings, zoning and special use requirements, net to gross area limits or projections, and any special considerations (e.g., required review processes by government or other review agencies). Soil borings, site surveys, and information about utility services should be a part of the program data as well.

6. *Architectural statement.* Just as the owner's intended use and teaching-administrative philosophy will significantly guide the formation of the program, so the architect's basic planning approach to the particular problem should be written and recorded as part of the programming process. While this could not or should not be developed until the architect has learned enough about the problem, its incorporation into the programming document can thereafter serve as an important guide for the others who will be involved in making decisions that should relate more clearly to a common philosophy and assure a more consistent and better end result. Also, for reviews by various approval groups, whether they be the school owner or a code official, having all the "whys" stated clarifies understanding and minimizes misinterpretation.

Summary

The architectural program then is the basis for beginning the building, and the more information collected at the outset, and properly evaluated, the more successful the planning process and end result will be. Time and thought carefully spent in programming will bring everyone's ideas together at the outset, give everyone a chance to make his contribution, and advance the project in an orderly manner.

FINANCING

Programming procedures and determinations quickly come to a collision course with financial limitations, and almost invariably the building program has to be adjusted to conform to the hard reality of financial possibilities. The nature of financing school buildings hinges on the type of school and its sponsorship. The job of getting the money is becoming increasingly harder as more complex government funding procedures come into effect, tax allocations are spread across consolidated districts, and the trend to more centralized control and management increases. Campaigns for bond issues and tax increases must become more effective, newspaper publicity, coffee klatches, and public to-dos must be more objectively organized to convince an increasingly well-informed, interested, but demanding public.

Both new communities and old residential-based communities have problems in funding new schools and programs because of the limits of assessed valuation of their total properties. This prompts a search for state and federal support and a concern about the possible loss of local prerogatives. New tax revenues are being sought within the communities by charging for more services and pursuing zoning changes toward a wider mix of community to accomplish a broader tax base.

Types of Financing

A given project will normally be in one of the following categories, requiring a related type of financing:

1. *School districts with taxing power.* Major building projects are financed by a bond issue referendum within the limits established by the differential between existing indebtedness and an allowed percentage of current assessed valuation of taxable property in the district.

2. *School systems under local government.* Project funds are received as appropriations which may or may not represent proceeds from sales of bonds by the governmental taxing authority.

3. *Private schools.* Funding is primarily dependent on bequests, contributions, and mortgage loans. Under special circumstances some facilities may be funded by federal agencies.

These categories, and the traditional methods of financing characteristic of each, generally apply to institutions of higher learning, as well as to secondary and elementary schools. Near exhaustion of traditional financing sources has led in recent years to the development of methods of supplemental aid or procedures for lifting the entire burden of capital investment from the school or institution.

Federal legislation provides grants-in-aid and self-liquidating loans to qualifying institutions through agencies of the Department of Health, Education, and Welfare and to a limited degree through agencies of the Department of Housing and Urban Renewal. State and local govern-

PRIMARY AND SECONDARY SCHOOLS

General

ments have assistance programs of their own. A growing trend is toward the establishment of school building authorities or commissions, which will finance and construct buildings for occupancy by a school on a rentlike basis, with costs paid out of operating income.

It has become a routine obligation of school administrators to keep themselves informed about all agencies and assistance programs which may be available to help in financing a project or, in some cases, to make traditional funding unnecessary.

Programming and Budgeting

Financing patterns have critical effects on the design and planning of school facilities. If the amount of a bond issue or an appropriation has been established prior to programming or detail planning, the scope of the project will be rigidly limited by that amount. The only flexibility then lies in a supplemental bond issue or appropriation, which is usually not feasible. If planning funds are available, programming and preparation of preliminary plans and estimates should be carried out prior to the establishment of a fixed amount of funds available for the project.

If assistance in financing is obtained from outside agencies, these agencies will become reviewing authorities with their own requirements and standards which will directly affect the implementation of the program. Such requirements may include any or all of the following:

1. A maximum allowable cost per square foot
2. A minimum required ratio of net instructional area to gross building area
3. Use of governmental specification standards
4. Specified bidding procedures
5. Designation of construction labor pay scale

In contemplating allowable costs for a proposed project, there must first exist a clear idea of all the costs involved. If there is a million dollars to spend, a million-dollar building cannot be built. The project budget must cover all costs related to the project which are chargeable to the capital funds available. A typical project budget would contain allowances for the following items:

1. Construction cost of building facilities
2. Site development and utility connections
3. Fixed equipment
4. Architectural and engineering fees
5. Contingency allowance

Additional budget items might include land acquisition, demolition of existing buildings, landscaping, movable equipment and furnishings, legal fees, special consultant fees, and miscellaneous special expenses. As a rule of thumb, in the average building project, construction cost cannot exceed three-quarters of the allowable project cost amount. If the project requires an unusual amount of furnishings and equipment, or if unusual site conditions add heavily to site-related costs, the allowable ratio for building construction cost will be correspondingly reduced.

THE LEARNING ENVIRONMENT

Economics of Comfort Conditioning

Business and industry have amply proved that people perform more efficiently in ideally controlled surroundings, and equally well support-

ed is the fact that financial savings have been made. Translating these arguments to the school situation, it can be said that if students learn and teachers instruct more efficiently in a controlled learning environment, more students can be educated in less time, hence at a lower cost per student. If the building is conditioned for effective 12-month operation and is made attractive for intensive community use, it can certainly be said to be more efficient and economically used.

Certain characteristics of building designs appropriate to total environment conditioning may, if the educational program permits, facilitate more economical construction, particularly if imagination is used in planning. The compact plan, for example, produces minimum exterior wall area, reduces piping runs, uses corridors and service areas most efficiently, and can be substantially more economical to build, operate, and maintain than other plan arrangements.

More and better use of the school buildings is, in itself, an economy to the community. Add to this the broadened educational and cultural advantages to the community at large, and it becomes apparent that the totally comfort-conditioned school is both practical and necessary.

Architectural Functions

The mechanical elements are the basic, but not the only, considerations for the entire job of climate control. The orientation, the plan arrangement, the design of the building, and the materials used can contribute to the quality of comfort achieved and to the economy (see Fig. 1). Consider the following:

1. *Plan.* Less room and exterior wall exposure in a compact, multistory building will cost less to heat and cool than a sprawling, one-story arrangement of equal area and cubage. A plan consisting of predominantly interior classroom spaces and peripheral corridors provides flexibility of space and economies in heating and cooling.
2. *Orientation.* Classroom windows facing east or west receive excessive heat from the sun. Although this fact assists heating in cold weather, the cooling problem is generally greater. As a general rule, it is preferable to face the majority of rooms north or south.
3. *Fenestration.* "Windowless" buildings are entirely practical: they save on initial cost,

maintenance, and heat loss and are free of outside dust, smoke, odors, and noise. Some windows should be introduced, however, to avoid that "closed-in" feeling. On the other hand, equally strong arguments can and have been made for the other environmental advantages of large window areas, the benefits of close relationship to the out-of-doors, and the welcome of light and sunshine to one's physical being.

4. *Solar controls.* Wide roof overhangs, solar screens, glass block, and similar devices to control sunlight are no longer as essential. The use of heat-absorbing glass reduces glare and light transmission and produces economies in the HVAC system design. Cleaner, simpler, far less expensive designs are now possible with uniform, high-level electrical illumination.

5. *Insulation.* Adequate insulation of roofs and exterior walls reduces both heat loss and heat gain far more than is generally supposed. Even double glazing adds measurably to more economical climate control.

6. *Space conditioning.* Skillful use of lighting, acoustic materials, and color and form in school design are essential ingredients of conditioning space in the learning environment and, properly applied, act upon our senses of sight and hearing to cause reactions conducive to better learning and teaching.

7. *Lighting.* Good lighting design involves locating illumination sources so that work areas receive adequate light free of glare and excessive contrast or shadow. Both natural and artificial light must be controllable to eliminate glaring shafts of sunlight or to darken the room for projecting pictures. It is desirable to use some incandescent lighting, strategically placed, to create points of variety and accent in the more conventional all-fluorescent systems.

8. *Acoustics.* Acoustical control involves containment, absorption, and reflection or reinforcement of sound. According to the circumstances of the listener, sound should be prevented from leaving a space when it will disturb people in adjacent rooms. Certain amounts of acoustically absorbent material must be used to "soak up" noise in such areas as corridors, toilets, and cafeterias. Accurate and comfortable hearing of music in an auditorium depends on projecting sound from reflection from some surfaces, but absorption in others to prevent distracting echos; a speaker's voice may have to be reinforced by an amplifier in large rooms.

9. *Colors.* Color is a psychological aid to learning. Tastefully used, it can enhance environment, engendering a cheerful, receptive mood. Bright, warm colors stimulate excitement and action in the gymnasium; soft, cool colors create a quiet atmosphere in places of study.

10. *Form.* The physical shapes of our surroundings also have psychological effects which can favorably influence learning. Large rooms, such as the library, cafeteria, or auditorium require higher ceilings, for a sense of airy freedom, than do small offices and conference rooms; corridors should be offset, widened occasionally, and given a view in order to avoid the feeling of interminable constricting length; an atmosphere of spaciousness, or lack of confinement, can be created by making some interior partitions of glass. This is particularly important when the plan design involves large areas of interior spaces, made possible by a climate-conditioned system.

By DON HALAMKA

SITE SELECTION

The farsighted school board will project its needs well into the future and select and acquire sites while land is still available and cheap. Such prudent long-range planning is facilitated by consultation with local county or regional planning agencies that possess knowledge and appreciation of the long-term system needs and growth patterns on community development. Frequently, large-scale development builders can be persuaded to dedicate land to community purposes well in advance of need with consequent savings to taxpayers. The following is a list of basic items for use in the selection of a school site.

- I. Present and future environment. Economic, social, and housing makeup of community
- II. Integration with community planning. Potential housing expansion relative to size, need, and location
Zoning requirements, limitations or restrictions
- III. Role in comprehensive school building plan. Relationship to high schools and other elementary schools in same district (township, county, or community)

IV. Site characteristics. Site location—urban, suburban, or rural (determines demand for minimum and maximum space required); percent of usability of site for building, recreation and playfields, parking, roads, and services; soil conditions—water table, flood plan, adjacent watersheds, and suitable materials for structural applications

V. Utility services. Utilities—availability and cost of electrical service, sanitary service (if none, feasibility of sewage treatment plant or septic tank); initial cost of land versus cost of land versus cost of improvements

SITE PLANNING

Analysis of Site and Surrounding Area

Site analysis, synthesis, and design are best developed by a team including the architect, landscape architect, and engineer working closely with the client. Using the checklist outline below, this analysis should be based on the specifics of the site and surrounding

area, the educational program, and community relationships.

I. Site analysis and evaluation

A. Location

1. Regional
2. Vicinity

B. Description

1. Size and survey locations
2. Existing conditions
 - a. Soils—classification and uses
 - b. Topography—contours and grade elevations
 - c. Hydrography—flood plain, watershed, streams, lakes and swamps
 - d. Structures—existing types, historic value or landmarks
 - e. Easements—widths and descriptions
 - f. Vegetation—type and size of materials
 - g. Utilities—sanitary, storm, water, gas, and electric
 - h. Wind and Sun—precipitation and humidity
 - i. Natural features and present land use

C. Zoning

1. Type and restrictions

D. Environmental conditions

1. Noise, vibration, and interference
 - a. Aircraft
 - b. Railroad
 - c. Auto
 - d. Commercial
 - e. Electrical
 - f. Radar
 - g. Industrial
2. Smoke and smog

E. Access road characteristics

1. Type—paved, unpaved, etc.
2. Width—paving and right-of-way
3. Volume—daily average and peaks
4. Planned improvements—widening, extensions, expressways
5. Traffic patterns—regional, city and local

II. Site requirements

A. Vehicular

1. Parking requirements
 - a. Executive
 - b. Employee
 - c. Visitor
2. Service
3. Maintenance equipment
4. Public transportation

B. Pedestrian

1. Circulation
2. Recreation

Fig. 1 Site analysis.

ELEMENTARY AND SECONDARY SCHOOLS

Site Planning; Busing; Parking

- C. Utilities
 - 1. Normal requirement
 - 2. Special requirement
- D. Miscellaneous
 - 1. Police and fire protection—distance, location, municipality, jurisdiction.
 - 2. Exhibit areas
 - 3. Community use

Land Use

Space Allocation Studies should incorporate all the elements and spaces required by the total developed program. In addition, any limitations which may be caused by specific site conditions should be noted.

Relationships The relationships of these proposed site elements and spaces to each other and to the site are best developed visually as diagrammatic studies such as those shown in Figs. 1 to 3.

Circulation

Circulation patterns are continuous from the points of access at property lines to and through the buildings and must be designed as integrated systems. Safety is important, particularly for lower age groups. For safe and efficient movement, separate each different type of circulation. Eliminate or minimize cross traffic between pedestrians and vehicles. Separate drop-off facilities for buses and automobiles. Service vehicles should be excluded from these drop-off areas; if this is not possible, use of service areas should be permitted only at times when pedestrians are not present.

Vehicular/Automobile Differentiate and provide for the three types of automobile traffic normally found on a school site: faculty, student, and visitor or parent.

Vehicular/Bus Give careful consideration to number, loading and unloading areas, site access, and storage of vehicles. Plan so that the backing up of buses is never necessary.

Vehicular/Service Service-vehicle access and loading and unloading areas should permit as short and direct an approach as possible with adequate maneuvering space. Service areas and access should be separate from other circulation systems.

BUSING

Magnet School Busing Study Figures 4 to 7 represent four (4) approaches to developing a system of bus parking and circulation. Presently, 36 buses will be required to provide transportation for 1,800 students to and from the school site (site area required for this service is significant—see land use studies).

Dimensions of buses to be considered are bus length = 36 ft 0 in.; bus width = 8 ft 0 in.; inside turning radius = 45 ft 0 in.; outside turning radius = 60 ft 0 in.; typical stall size = 12 ft 0 in. \times 14 ft 0 in. Buses should not be required to back up. (Tables 1 and 2.)

TABLE 1 Auto Number and Space Requirements*

School	Parking spaces
Elementary	One per classroom + 3
Junior high	One per classroom + 6
High school	One per classroom + 16

* Space requirements average 350 to 400 sq ft per automobile, depending on parking angle. The most efficient is 90° parking.

Fig. 2 Land use diagram.

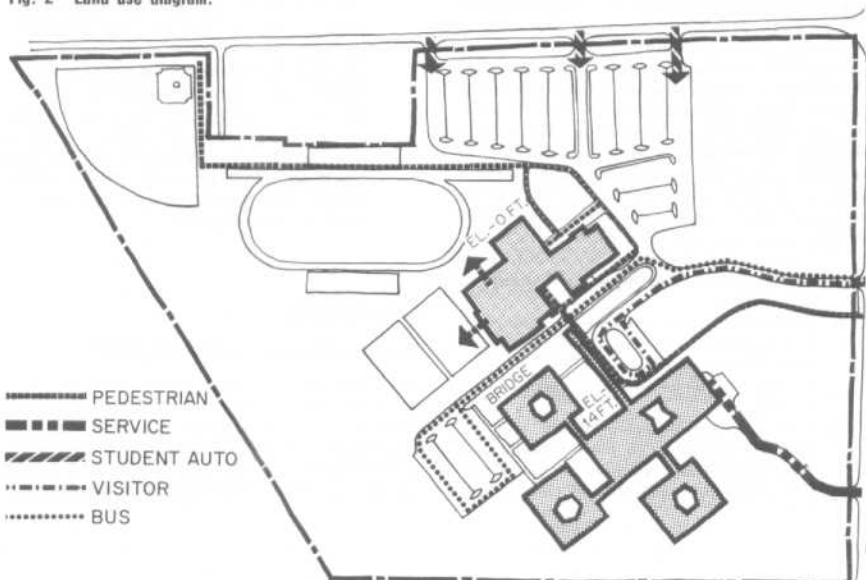

Fig. 3 Site circulation plan.

People

Safety is most important. Walkways of all-weather, nonskid materials, well delineated and arranged to eliminate or minimize conflict with vehicle circulation can be both safe and pleasant. Where changes in grade are necessary, a ramp is generally preferred to steps and the incline should not exceed 5 percent especially where snow and ice are expected.

PARKING

There is usually merit in separation of the three types of automobile parking, with the daytime visitor taking precedence over faculty and student. Parking facilities should be located to consider all their uses, including daytime uses for visitor, parent, faculty, or student, uses for school-related or community events within the school building, and uses

TABLE 2 Comparison of Busing Study Data

	Minimum width required	Lineal feet required (for 36 buses)	Area required per bus (includes circulation), sq ft*
Parallel single file	12 ft 0 in.	1,584	528
Parallel free access	25 ft 0 in.	2,736	1,900
30° peel-off	55 ft 0 in.	860	1,320
30° free access	65 ft 0 in.	860	1,572
45° peel-off	65 ft 0 in.	620	1,100
45° free access	85 ft 0 in.	620	1,440
60° peel-off	85 ft 0 in.	510	1,164
60° free access	115 ft 0 in.	510	1,584

* Data are approximate.

ELEMENTARY AND SECONDARY SCHOOLS

Busing; Parking; Recreation Facilities

Fig. 4 Parallel bus parking system.

Fig. 5 30° bus parking system.

relating to various outdoor athletic events. Overflow parking areas may double as paved play areas when properly designed and located.

Access to parking facilities and arrangement of parking lanes should minimize conflict between automobile and pedestrian. Collector walks should be provided and arranged to permit pedestrians to exit vehicle areas as directly as possible (see Fig. 8).

RECREATION FACILITIES

Site Location Considerations

These criteria for recreation areas, such as relation to adjacent property, soil stability and percolation, existing vegetation, existing topography, etc., are important; however, special attention should be given to the need for large open spaces for field games with adjacent existing vegetation to provide shade, oxygen, and windbreak. In dense urban areas, where ordinary open spaces are scarce, such field facilities can be created on air rights, rooftops, and terraced slopes. Informal play areas, especially for the lower grades, can be created in multilevel arrangements conforming to a steep site; this is not possible with field

Fig. 6 45° bus parking system.

recreation facilities for the contact sports enjoyed by upper grades. Superimposition of layouts and multiuse helps conserve space when land is at a premium.

Recreational Facility Layout

One of the best approaches is to construct scale templates (1 in. = 50 ft for most site planning purposes) of all facilities considered in the school program. These can be drawn on tracing vellum, using official court and field dimension layouts as a guide. Cutouts can be used for shifting locations on site plan to determine optimum layout. Construction and funding phasing and types of multiuse can also be developed using these templates.

In creating a unique layout for a site, consider these factors:

1. Optimum orientation for sun and wind control
2. Circulation for players and spectators
3. Buffer zones between action spaces
4. Access from showers, classrooms, student and spectator parking, and buses
5. Access from community where multiuse is possible
6. Flexibility of layout and accommodation of staging or building expansion
7. Programming of play and learning experiences for younger children

TABLE 3 Analysis of Playground Surfacing

From School Sites, No. 7, U.S. Dept. of Health, Education, and Welfare.

Type of surface	Year-round utility use	Qualities								
		Multiple use	Dustless	Fine-grained, nonabsorbent	Durable	Resilient	All-weather footing	Reasonable cost	Low maintenance	Pleasing appearance

ELEMENTARY AND SECONDARY SCHOOLS

Recreation Facilities; Safety

8. Supervision and safety
9. Compatibility of age groups, sexes, and type of activity in contiguous play areas
10. Grading and slope for drainage (or underdrainage)
11. Existing relationship to nearby community facilities
12. Need for balance of action spaces with provision of quiet open spaces

Suggested Facilities According to Age Groups and Grade

• Kindergarten to third grade: Sandboxes, sand trays/cans, slides and tunnels, swings, tree houses, climbers and steppers, trike and bike riding, water features.

• Fourth to seventh grades: Climbers and jungle gyms, shuffleboard, hopscotch, informal group games, little league ball, softball, spider webs and trampolines, adventure playgrounds with junk building materials.

• Eighth to twelfth grades: Softball, baseball, football, touch football, soccer, volleyball, tennis, archery, track and field events, rifle range, physical fitness workout course.

Materials for Recreational Surfaces and Structures

Effect of low-maintenance synthetic surfacing and structural materials is significant. Their increased durability under intensive use makes multiuse and community use feasible. All-weather surfaces maximize use; cleaning by hosing, vacuum, and snow blower minimize maintenance. Durable yet flexible play surfaces allow use in cold or wet weather without injury to surface or players. Regrading, reseeding, fertilizing, aerating, spraying, mowing, and weeding are eliminated.

Fig. 8 Parking area circulation.

DRAINAGE

Proper storm drainage is essential to successful school-site facilities in most areas of the country. Not only do the function and longevity of many facilities and materials depend on good drainage, but in some cases permanent damage may result from water. Surface and subsurface systems or combinations should be designed to adequately handle the needs of buildings and site facilities. Where possible, an overland emergency system should be incorporated, using the relative grade elevations of the site. When circumstances do not permit this, a standby system of pumps or power generators is recommended.

PLANTING

Select materials indigenous to the area where possible, and supplement with ornamental materials that possess characteristics not obtain-

able with local materials. Plant materials should also have low maintenance requirements and be compatible with existing growing conditions. Plant material for school sites generally consists of shade trees, ornamental trees, evergreen trees and shrubs, deciduous shrubs, vines, and ground covers (see Fig. 9). Though some of the ground-covering material on most school sites functionally is mowed grass, this material remains one of the highest maintenance types. It is recommended that its use be kept to the necessary minimum and the use of meadow and prairie grasses and other types of ground-covering materials be considered. This is particularly important on sites where appropriate ground cover material exists and should be carefully preserved. Select plant material on the basis of its mature size and character to minimize excessive shearing and early replacement. Initial sizes should not be less than a reasonable minimum to ensure survival from injury or damage by students and other causes. In addition to providing an aes-

thetic contribution plant material on the school site can be used to solve many problems such as windbreaks, screens and buffers, sound dampers, sun and light controls, erosion control, and air purification.

SAFETY

Schools, by the nature of their occupancy and use, require higher standards of safety than other types of buildings. Provisions for life safety have the highest priority and affect the entire design in plan, construction, and choice of materials. All phases of health and safety become pervasive program elements that unavoidably add to the complexity and cost of schools and greatly determine their form and plan organization and appearance.

Building codes generally have separate and specific requirements for school construction. Many states and counties have school safety codes established by departments of education,

Fig. 9

ELEMENTARY AND SECONDARY SCHOOLS

Safety

health, and public safety. Architects and engineers are obligated to inform themselves of all reviewing authorities and applicable codes in a given locality. In the absence of adequate local codes, standards of the National Building Code, the National Board of Fire Underwriters, and/or the BOCA (Building Officials Conference of America) Code are good guides. The following are some of the safety considerations of concern:

- Structural safety
 - Material strengths and factors of safety
 - Fireproof and fire resistive structures
 - Windstorm resistance
 - Earthquake resistance
- Fire safety
 - Provision and protection of exits, corridors, and stairs
 - Fire detector and alarm systems
 - Sprinkler systems
 - Materials and finishes with low flame-spread rating and Nontoxic combustion characteristics
- Health safety
 - Ventilation systems and standards
 - Lighting standards and electrical code
 - Plumbing fixture requirements and plumbing code
 - Swimming pool and locker room requirements
- Special emergencies
 - Emergency lighting systems
 - Air raid shelter and radiation protection
 - Tornado protection and shelter
- Accident protection
 - Nonslip surfaces (especially stairs, ramps, locker rooms, pool decks)
 - Vision panels, door swings and hardware
 - Hand rails
 - Safety glass in doors, sidelights
- Handicapped provisions
 - Required accommodations at entrances in circulation provisions, toilets, and other public accommodations for use by handicapped persons.

Sensible corridor planning and location of stairs and exits to handle traffic flow without congestion will usually provide appropriate fire exit facilities. However, codes must be checked to ensure proper corridor widths, corridor lengths, and smoke barriers at suitable intervals. Stair enclosures are required for all stairs connecting more than two levels and are recommended for stairs generally. Most stairs are used for exit purposes and have detailed code requirements which must be met such as width and ratio of tread-to-risers.

School Exits

Exits and emergency exits should be clearly marked so that at no time is there any doubt or

Fig. 11

hesitation as to their purpose. A sign indicating the nearest exit should be visible from every point in the corridor. Two or more exits should be provided from any area within the school. Some states require two exits from each classroom.

It should be possible to open every door from the inside at all times, even after school is closed for the day.

A well-defined exit will include a lighted red exit sign and a white security light connected to an emergency power supply in the event of main power failure.

Fig. 12

Stairways

One of the most critical parts of school traffic design is the stairway, which should be located in relation to the overall traffic pattern, keeping in mind load distribution, safety, destination of students between periods, and elimination of cross traffic. The stairways should be designed for easy, fast, and safe movement of boys and girls.

Stairways not only provide egress to and from various floor levels, but they are used every period for the vertical circulation of students changing classes. It is important that stairways be designed so that boys and girls with books under their arms may walk side by side to avoid congestion; a width of 4 ft 8 in. to

5 ft between handrails is recommended. Stairways should be of fireproof construction, leading directly to the outdoors. They should be provided with smoke-control facilities, separating the stairwells from the corridors which they serve.

Corridors

A well-designed school has corridors that accommodate the free and informal movement of students. The narrow corridor usually requires formal, regimented, and supervised traffic flow.

The walls of corridors should be free of all projections. Heat units, drinking fountains, fire extinguishers, lockers, doors, and display cases should be recessed in the interest of student safety (Fig. 10).

Acoustical properties are desirable to reduce hall noise. Corridors should be well lighted, with emergency provision in the event of main power failure. Floor covering should be durable, nonskid, and easy to maintain.

The maximum length of unbroken corridors should not exceed 150 to 200 ft. Longer sections give an undesirable perspective.

Stair Treads

Standard dimensions of stair treads and risers should be used in schools. Odd dimensions increase the stair hazards for children as well as adults. Wax used on classroom and corridor floors may be deposited on stair treads by students' shoes. One way to reduce this hazard is to design a tread that will give traction regardless of wax application. Inserted carborundum treads have proved adequate (Fig. 11). Surface-mounted strips are unsatisfactory.

Handrails

Handrails are necessary on both sides of stairways in accordance with the National Building Code. They should be installed with attachment brackets permanently anchored in the masonry wall (Fig. 12). Brackets anchored with lead, wood, or leather expansion bolts often result in unsafe support and considerable maintenance.

Doors

Boys and girls are not expected to use caution in opening and closing doors. The hazard of striking students with doors can be reduced by including a vision panel in the door (Fig. 13) and by recessing the door. The location of this panel should be in proportion to the varying heights of children. Use of tempered or wire glass will provide safety.

Vision panels placed next to doors allow students to see someone approaching the door from the opposite direction. These panels should be designed with opaque sections near the floor and mullions at suitable intervals to clearly identify them as windows, not passageways.

Covered walkways to accommodate inter-building traffic should be designed to protect students and not for appearance alone. The roof deck should be wide and low. Provision should be made to carry off roof water. Proper outside lighting will be necessary under the roof deck.

Some current trends in school planning such as the open-plan concept depart from traditional room and corridor arrangements and raise new problems in preserving a protected route of exit from all parts of a school building. Attempts to make use of corridor areas for instruction, study, or special purposes must be carefully planned to maintain a clear traffic lane free from obstacles or disruption by movable equipment and furnishings.

Fig. 10

ELEMENTARY AND SECONDARY SCHOOLS

Safety; Kinds of Schools

Fig. 13

Efforts to minimize barriers between instructional areas and corridors by glazing with ordinary glass or by eliminating portions of corridor walls run counter to traditional safety requirements, but have been accomplished through special provisions of sprinkler systems, plan organization, and building material use. Open planning for large instructional areas accommodating several groups with no designated corridor areas and with flexible divisions provided by movable partitions and divider units also presents special problems of safety. Since many codes were written before this educational concept became popular, planning of this type will require conferences and cooperation with public safety officials to obtain agreement on acceptable provisions for safety.

Some safety considerations, such as avoidance of risers at entrances, also relate to the needs of the handicapped and the temporarily disabled. Low-pitch ramps instead of stairs at changes in level can be a safety feature as well as a service to the physically handicapped and an aid to the movement of maintenance equipment and supplies. Special additional provisions for the handicapped should be made in toilets and other areas.

Secondary to life-safety considerations, but still a major factor in school design, is the preservation of building integrity and security. Fire insurance bureaus establish requirements of building design and construction which must also be checked for the safety of the occupants and for qualification for reasonable rates of insurance. External security should be provided by night illumination of the area around the building and by other electronic systems. Problems of vandalism are increasing with exterior glass a particular target. Currently, glass areas are being reduced along with the trend to air conditioning, and new types of plastic glazing are being used.

While most responses to the various safety-factor requirements are quite obvious, commonsense planning and aesthetic consideration can make schools more safe in other ways. The particular use of colors and materials can produce an aura of serenity and order in themselves. A plan of sure clarity can minimize confusion and make circulation patterns clearer. Carpeting and other acoustic provisions can reduce noise and distraction. Materials that are attractive but easily maintained will allow a cleaner and safer school. And, lastly, the attitude of those learning and teaching in the school can make it safer. A clean, well-done, well-run, and "happy ship" school is a safe school.

KINDS OF SCHOOLS

There are different kinds of schools, functioning as organizations of students and faculties, that serve various age groups and certain purposes. There are also different kinds of school plans, or ways of organizing the needed space to better respond to the ways of teaching certain age groups and to other requirements such

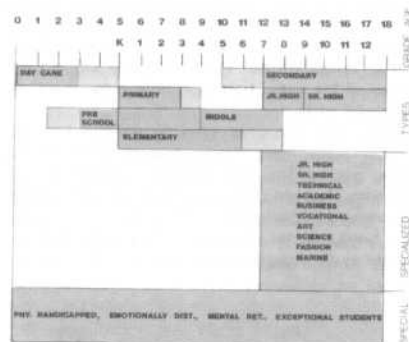

as site and climate conditions, construction and funding phasing, and code restraints.

Organization of Students and Faculties

Time, location, organization, method, and semantics all have had their influence on schools. Sometimes a school's name has little to do with what the school is. There are still grammar schools, but most of this category are now called elementary schools. Secondary schools usually denote grades 9 to 12, but this category now encompasses junior high and middle schools, depending on program and organization. Kindergarten at one time was preschool education. Now almost universally, it has become a part of the elementary school's program. Preschool education can be divided into a number of types: day care, nursery, and Head Start.

There are community, central, neighborhood, regional, vocational, technical, academies, academic, and special schools. All these schools include education before higher education. Even the definition between lower and higher education is now being reconsidered, with the first two years of college and junior college being thought of as the thirteenth and fourteenth years of public education.

Because of the overlapping names, grades, levels, and age groups, the following list of descriptions and Fig. 14 might make this maze somewhat clearer.

• Day care: Serves the dual function of providing a custodial or care center where working parents can leave their preschool child and providing group learning experience for the child.

• Nursery: May serve the same function as day care, but frequently provides only the group learning experience.

• Head Start: The same function as day care and nursery for socially deprived children, with emphasis on program and experience to remedy or prevent the problems of such deprivation.

• Kindergarten: Usual type of introduction to group learning experience in elementary schools.

• Elementary: Traditionally covers K-8.

However, more frequently in recent years it covers only K-6 with junior high or middle schools experience for the last two years.

• Primary: The earlier years of elementary education, usually K-3, sometimes K-4.

• Middle schools: Usually grades 5-8, sometimes grades 4-8, combining both secondary and elementary pupils. Program is frequently structured as a secondary school.

• Secondary schools: This category includes middle schools, junior high schools, and senior high schools, grades 5-12.

• Junior high schools: The earlier years of secondary education usually grades 7-9, sometimes grades 7 and 8.

• Senior high schools: The latter years of secondary education usually grades 9-12, sometimes grades 10-12.

• Special schools for secondary education: These schools are usually found in large urban areas or in more rural areas as special regional schools. They provide a special curriculum for such studies as vocational training, business, art, drama, science, marine, and fashion and design.

• Special schools: Schools for children who do not fit traditionally into the normal school programs. These schools are for emotionally and physically handicapped, the mentally retarded, or the exceptionally bright.

• Community schools: Community use of the facilities for programs other than the normal school program. This can range from the limited use of a gymnasium for basketball at night to a building that could house social agencies; health agencies; extensive youth programs; and programs for the elderly, social guidance, public assistance, legal aid, etc.

• Neighborhood: Generally means smaller schools identified with a specific neighborhood, where busing is neither necessary nor desirable.

• Central schools and/or regional: Generally found in rural areas where population density does not support adequate school facilities. Children are bused for great distances to allow them to attend facilities that offer them broader program and opportunity.

• Urban: Urban schools can be any of the above, but some new innovations are such things as storefront academies.

• Storefront schools: These schools identify with the people of the street in heavily congested urban areas. Such schools do away with the traditional atmosphere. They relate to the dropout and other youth who are alienated from the traditional institution.

• Schools without walls: In downtown urban areas, schools use the facilities of community space, office space of business organizations, public libraries, etc.

Organization of Spaces

There are many ways to organize the spaces for a school into a plan, and many determinants to consider, beginning with the basic purpose of the specific teaching program and the children to be served. But even this basic premise may have to be considered in the context of how flexible the plan may be made to anticipate the possibility, or rather the probability, that the school could convert to some other organizational structure.

Pupil Capacity

Elementary Schools Before any calculation of school capacity can be made, the school system must have an educational policy establishing the optimum capacity of classrooms. In many schools this figure is set at 27 pupils, which, when used as an average class size, may mean that some rooms will exceed this number.

ELEMENTARY AND SECONDARY SCHOOLS

Kinds of Schools

Kindergartens may be set at 20 pupils in each of the morning and afternoon sessions.

Some schools do not like to exceed 25 pupils per class. It is frequently recommended that when a class goes to 32 pupils it be divided into two sections with two teachers. It is also advisable in determining the capacity of an elementary school to consider each grade separately so that there will be no single classroom housing more than one grade.

High Schools Determining capacity on the secondary school level is considerably more complex than on the elementary school level. Capacity in a good secondary school reflects the kind of educational program and the educational goals of the community. (See Fig. 15.)

The character of the classroom and the subject are determinants of the classroom size. Physical education classes may run to 35 or 40 students; shop classes should not exceed 20 students. Many other areas should not exceed 25 students and might, more likely, hold 20 pupils, including science rooms, homemaking, and fine arts. These class sizes may be adjusted from community to community, but for comparative purposes it would be helpful to maintain a standard formula for determining capacity (Table 4).

Flexibility and the Open Plan

Indeed, flexibility has become a most critical consideration, reflecting the continuing changes in educational thinking and building techniques. The open-plan concept derives from a dramatic change from the self-contained classroom to various size spaces to accommodate groups working together and separately, and also from the development of dramatic improvements in lighting and ventilation techniques, acoustic and long-span structural economies, and the total economy of better utilized space.

What is required by users and authorities is a real breakthrough in attitudes toward the sharing of a total space by a large group of different ages so that the space can be constructed with few or no ceiling-high partitions, without any special concern for being near windows, and with no especially designated bands of space for circulation.

In fact, the open-plan concept responds to a looser, more relaxed society with more confidence in the group, and to the totality of the school's objective of enabling people to get along with each other, and to the step-by-step progress of democracy: an individual into a group, a group into another, into the whole.

As with many ideas in education, the open-plan concept has begun at the elementary school level and has yet to extend appreciably beyond to where concepts of specialization begin, spaces are more especially planned, and innovations are more slowly realized. Such areas of specialization, like science, bring together people of specialized interest and require the use of specialized equipment or teaching techniques that make more difficult the realization of new, combined approaches.

TABLE 4 Classroom Capacity for High Schools

Type of space	No. of units	Capacity of units	Total capacity
Classroom	19	x 27	513
Science laboratory	3	x 25	75
Commercial education	4	x 25	100
Home economics	2	x 25	50
Art	1	x 25	25
Shop	3	x 20	60
Band or chorus	2	x 35	70
Gymnasium, playroom	1	x 35	35
Gymnasium with partition	1	x 70	70
General education laboratory or study hall		x 35	
		Maximum capacity:	998
		Optimum capacity at 80 per cent utilization:	798

Working Space Relationships

Successful planning puts together the parts in such a way that they work well together. As the open-plan concept responds to a way of teaching and a way of efficiently using space, any good plan stems from and assures efficient function by responding carefully to the educational program and matching it with a logically engineered building expression. Circulation should be as direct and minimal as possible, directed to an efficiency of the total plan to allow for the incorporation of amenities to give the school some special qualities.

The sections following on special areas define their own requirements as part of the total program and further illustrate relationships within their specialties. Circulation to

Variety in Plan Concept

The plans shown have been chosen for the differences they illustrate, simply because many factors other than purpose and function affect and determine the concept of a plan. Some are compact and chunky, containing large amounts of interior, mechanically ventilated spaces for reasons of internal relationships or ultimate use of restricted site. Some are cluster plans using units connected by circulation links to resolve a plan into a series of smaller pieces to give the school better scale, to allow small children to respond better, to relate better to a neighborhood of homes, and to fit better to changing terrain.

Other plans group their parts to resolve a large school into component communities of

Fig. 16

the school and within the school along with the physical needs of the spaces establishes the plan concept. The plan examples shown vary in total concept yet work as entities in the relationship of their parts.

students. Others especially relate to unusual site conditions, place emphasis on unique circulation requirements, and respond to the need of incremental expansion of classrooms or core elements. Chosen to represent such differences, the examples shown collectively reflect a major trend in school buildings, as in all buildings: a trend away from finger plans or narrow building units dependent on windows toward large plan areas divisible into many combinations, more efficient in usable area, developing less perimeter wall, and generally representing more value for the cost to build, to utilize, and to operate.

Elementary Figure 16 shows a city school of three units, four stories high, dependent on simple stair circulation. Most classrooms get

FACTORS AFFECTING UTILIZATION OF CAPACITY

Fig. 15

ELEMENTARY AND SECONDARY SCHOOLS

Kinds of Schools

Fig. 17

corner orientation, minimum corridors, simple convertibility to open-plan clusters, efficient site utilization, and repetitive construction.

Figure 17 shows an open-plan concept of spaces for small groups arranged around large group instructional areas for three age groups in turn related to a central study-resource center. Administration and other shared spaces wrap around school court entrance area.

Figure 18 illustrates a cluster plan of divisible classrooms arranged by age groups sharing central entrance areas, relating to shared spaces, and resulting in a plan of residential scale and noninstitutional interiors.

A two-story school, a near square in plan, is shown in Fig. 19. Its lower level accommodates the more fixed elements of special function

requiring special services. The upper floor accommodates the more typical, simpler spaces like classrooms and library and has the potential for complete flexibility around the stair and toilet cores.

In Fig. 20, there is an efficient, one-story plan of alternating classroom clusters opening to private courtyards and connected by a main circulation aisle. Shared facilities are centered in the plan for easy public access through the large entry court.

Figure 21a shows another special city school for ages 3 to 14 on a limited site, three floors, with large corner open-plan spaces for group instruction related to a core space for faculty and seminar use. Rooftops of a related parking area and a communicative arts center are used

to supplement the site's minimal play area.

Figures 21b and c show the communicative arts unit, a centered experimental theater surrounded by art studios of adaptable, divisible space with service utilities on the inner perimeter.

Junior High—Middle Schools The plan shown in Fig. 22 was developed for a narrow city lot, and compactly radiates its parts out from a central activities court. The specialized and public-oriented facilities are all on the ground floor, while stairways at the four corners serve the upper floors of typical classrooms that ring the courtyard.

Figure 23 is a two-story middle school with classroom/laboratory blocks related to a central resource area. All the major units are well articulated, with stair units on the edge of or between flexible units of space. The pool is a later added unit and illustrates the ability to successfully expand such a concept. Figure 23b is the upper floor academic unit, illustrating a classic and basic grouping of classrooms around a large, shared lecture room.

High Schools Figure 24 shows a campus-type plan resolving a relatively large school into smaller elements. Classrooms are grouped around interior laboratory and lecture facilities, and the library is the academic focus; gyms and auditorium are in separate buildings of structures appropriate to their function, as are the academic elements.

Figure 25 demonstrates a basic disposition of functional elements in simple, economic blocks of spaces organizing its public and major entrances to the left, and focusing its emphasis on a pleasant circulation-flanked court to which the learning resource opens.

Again, simple large blocks of space, in Fig.

26, in a compact plan on a restricted city site, connected by a see-through, central, two-story unit of cafeteria, study and lobby and balcony circulation (toned area) and library at the second level. Terrain and grading of site allow academic units to exit without stair units. Form articulation develops a scale compatible to the neighborhood's apartments.

Figure 27 is a school that has been added to many times; its most recent and substantial addition enlarges it from a school for 2,400 students to 6,000 students. The plan expansion develops around courtyards and resolves itself into four subschools, or houses, of 1,500 similar academic facilities, with shared facilities expanded to serve the total. Each "house" of 1,500 has its own resource center, study, and dining facilities, as well as core classrooms giving the students a better sense of identity and scale for learning.

Vocational High Schools A typical floor plan of a high school for business instruction (Fig. 28) is located approximately in a ten-story building in a downtown location. Designed as an office building to expand vertically, it has flexible space around the core of circulation and mechanical requirements. Additional elevators can be accommodated in spaces next to the existing elevators.

Figure 29 proves that vocational schools can indeed be exciting in concept. This plan groups its major shops efficiently in two wings and slashes through a ramping diagonal connecting the changing levels of the site.

The portable or prefabricated classroom (Fig. 30) is a good and useful idea that has developed a somewhat bad reputation. Designed to be temporary, it too seldom has been removed or replaced or refurbished. It remains, however, a good idea to serve temporary peak enrollment loads. Many such facilities are available, and their quality is improving.

Administration Suites

Fig. 30

Fig. 31

ADMINISTRATION SUITES

The administrative spaces for a school, whether it's a single office for a teaching principal and a part-time secretary or a battery of offices for a huge high school, are the control center for the school and contact point for parents, students, and faculty alike. Here the school records are kept or reviewed, the ubiquitous public address system originates, budgets are developed, books and records are kept, and counseling and discipline are meted out. It is a first contact point and a crossroads check-point and is most always placed near the main entrance, and belongs there.

Essentially it is an office, or a group of offices, conference rooms, work storage rooms, record storage, and money vault. Opening to the entrance lobby, Fig. 31 shows a well-developed suite for an elementary school, containing the basic administrative offices and areas for typical related activities. Figure 32 shows a more extensive development for a junior high school, with added typically related space for counseling offices. Figure 33 shows a high school suite, where counseling occurs elsewhere, but with other facilities and a close relationship to the resource center. Figures 34a and b are details for faculty mail boxes, allowing service from one side and access from the other.

Figure 34c shows another high school office suite including counseling and space for

faculty carrel units. Figure 35 develops in a linear plan. Figures 36 and 37 show the basics needed in a faculty office, and Fig. 38 is a unique variation that groups four faculty offices as an island space, with non-ceiling-high partitions, set in groups in a large resource center space for closer contact with the students.

In school planning particularly, the area for office use is carefully dispensed in relation to all the other space needs and since the public is sometimes suspicious, careful planning

Learning Resource Centers

and choice of efficient equipment are especially important; minimums are almost invariably exercised, but common sense should be too. A few suggestions: fireproof files for records are less expensive than a fireproof vault; disciplinary offices and waiting rooms should be kept separate from the administrative waiting room for psychological (student) reasons; and teachers' mail should be private but easily accessible.

LEARNING RESOURCE CENTERS

Library may be yesterday's term for yesterday's services, for the school library has become the information and resource center for the school, and is more appropriately and now commonly called learning resource center (LRC), instructional materials center (IMC), or information resource center (IRC). In addition to books and periodicals there are now records, tapes and cassettes, closed-circuit TV programming and production, film, cameras, and projection equipment. Alongside the book stacks, chairs, and tables are sight-and-sound-equipped study carrels, listening rooms, earphones and program selectors, film splicers and slide-making equipment, preview rooms, even television studios. It is a supermarket of media and a place for its active use, but its ultimate use could be anywhere and everywhere (Fig. 39).

The resource center is now indeed where the action is and should be physically and educationally at the heart-center of the school, as equally accessible as possible to the classrooms, the laboratories, the administrative offices, and the community. It may well be open after school hours and should be located to allow direct access to it.

While the resource center is now a conglomerate of materials and services and successful planning seeks the mixture of these for the convenience of the users, control of the materials becomes a greater concern and problem, along with well-related backup preparation and work space. The circulation of the users, the administration of the materials, and the functional accommodation of the materials are the basic planning determinants.

The examples illustrated show various combinations of elements, the constant of the control desk and its more usual relationship to workrooms, reference-periodical areas, and offices. Added required exits are treated as emergency exits with alarm provisions. Areas allocated for books and seating are usually prescribed by state agencies or follow recommendations of the American Library Association. The total program may best be developed with a consultant in the field who is fully aware of equipment needs, current developments, and the proper relation of a program for the resource center to the entire school curriculum.

Though the idea of a quiet reading atmosphere has not been forgotten, the resource center has become a pleasant, busy goldfish-bowl kind of place: glassy, on display itself, extending its welcome to students as a comfortable place they like to learn in. Whether it may be considered a resource center or still a library, whether it is an alcove off the lobby, a room, or a maze of parts, the real goal is to get the students to use the materials and to learn. Carpeting has become very common, and other surfaces are being upgraded, resulting in good looking functional finishes to which everyone responds well.

A resource center for a 1,000- to 2,000-student high school, Fig. 40 well illustrates the many kinds of facilities that can be included,

Fig. 44

the mixing of stacks with group study tables and study carrels, a teacher material preparation area, and a central nerve-control center.

Figure 41 shows a typical carrel unit and detail equipped for audio-visual use. Grouping four together in this manner saves space and is a useful alternative to wall perimeter units.

Responding to the scarcity and high cost of land in certain communities, Fig. 42 shows a center that connects to an existing building, but is air conditioned and all below grade, with its roof developed as landscaped or play space. It also responds 100 percent to the concern by some about windows in the resources center which reduce the wall perimeter for book shelving and other uses.

Accommodating books remains a basic problem in the desire to visually "open up" a resource center; capacities can be gaged from the illustrations in Fig. 43 and Table 5.

A two-level high school resource center is shown in Fig. 49 with entrance (and control) at both levels bringing the center's services closer to more of the school. An opening in the second level and generous stairs between levels unite the spaces that open to an enclosed court.

Figure 45 shows one of four learning resource centers for a high school of 6,000 students that has been organized into four subschools of 1,500 and related groupings of core classrooms. Unique is the accommodating of faculty offices within the study-resource area in group units of non-ceiling-high glass partitions and book shelving units. This develops a close teacher-student relationship and a counseling to the typical resource center by persons expert in specific subject areas.

CLASSROOMS

The classroom layout in Fig. 46 represents a standard size room with a recessed corridor door and a standard seating arrangement.

Figure 47 shows a room designed for ten to fifteen pupils. Rooms of this size can be used for a variety of purposes, such as conference room, student council room, or for small class groups.

The development of the teaching process, extension of classroom activities, and use of group techniques within the classroom have led to new classroom design in recent years. Square classrooms have been proving more satisfactory than rectangular ones. The area of the classroom is increasing with the realization that small classrooms of the past have been the greatest handicap to the improvement of the educational program.

The large group lecture and demonstration room in Fig. 48 is provided with 64 tablet-armed chairs. Proximity to the demonstration table is important for all students. Seats should be tiered for better visibility. In the case of science demonstration, the demonstration table should be immediately adjacent to the preparation room. Natural lighting is generally undesirable but, if required, provision should be made for automatic operation of blinds. The light switch should be near the demonstration table.

Recommended classroom sizes for elementary schools range from 850 to 1,150 sq ft. High school classrooms may range from 750 to 900 sq ft. In some instances where large group teaching or team teaching is taking place, double classrooms may be desirable. In other instances, regular classrooms may be divided by the use of a folding partition which has a satisfactory acoustical separation.

ELEMENTARY AND SECONDARY SCHOOLS

Classrooms

General Requirements for All Classrooms

Design

1. Sufficient space is needed near the front of the room for setting up audiovisual equipment, such as projection screens and charts.
2. Ceilings should be a maximum of 9½ ft high.
3. Light from windows should, if possible, come over a pupil's left shoulder. No teacher should be required to face the windows when addressing the class from the normal teaching position.
4. Ceilings and/or walls should be acoustically treated.
5. Floors should have a cushioning material.

Location The classroom should have as quiet a location as possible, away from noisy outdoor areas. Ease of access to specialized facilities outside the academic unit should be ensured.

Light Control Color films, television, and slides are becoming more and more widely used. Darkening curtains or light-tight blinds should be provided for light control in all teaching areas. The architect should give careful consideration to the problem of darkening clerestories, skylights, and other sources of light. Consideration might be given to the type of venetian blinds that ride in side channels and are easier to operate and to clean than other blinds.

Electrical Services

1. A double electric outlet should be located on each of the three interior walls, and above all counters for use with equipment such as projectors and phonographs. Locations near sinks should be avoided.
2. Eight-inch clocks should be placed in all educational rooms.
3. A fire-alarm system is required.
4. Light switches should be located at the door. It is suggested that switches for corridor lighting be located so that pupils do not have access to them.
5. In planning the building, consideration should be given to ease of wiring a coaxial cable for television, if it will be needed later. Conduit is not recommended, but access to furred ceilings above corridors for this purpose would be desirable. Television reception from broadcast stations may be desirable in large group classrooms. Antennas might be provided here and at other selected points in the building.
6. Telephone service will be required to administrative offices and to other critical points in the school.

Doors

1. Doors should be placed at the front of the classroom and should be recessed so that they do not protrude into the corridor.
 2. Thresholds should be avoided so that equipment on wheeled tables, such as mounted movie projectors, can be rolled in and out easily.
 3. All doors should have a vision panel of tempered or wire glass.
 4. Door hardware should be such that doors cannot be locked from inside the classroom.
- Two large classrooms separated by a movable partition are shown in Fig. 49. When the folding door is open these rooms become an assembly room or an area for large group instruction. Caution should be exercised when selecting a folding door. It should be easy to operate and it should provide suitable acoustical properties. Rooms of this type should have two exits, one for each area.

ELEMENTARY AND SECONDARY SCHOOLS

Classrooms

Fig. 46

Fig. 47

Fig. 48

The split-level plan of the Dundee Elementary School in Greenwich, Conn. (Fig. 50), shows classroom space needed for a team-teaching program. Team teaching, a relatively new technique, is being used in both the elementary and the high school level. The principal requirement for building facilities in team-teaching programs is flexibility—the ability to have space for small, average, and large-size classes, and to be able to shift these spaces from hour to hour. In this type of school the rooms may be constant or variable in size, and in both categories there are small, average, and large-size groups. The illustration indicates how this has been done by the installation of electrically operated folding partitions in many of the rooms. Under this program the movement of pupils is generally much greater than under the homeroom type of elementary program. Ample corridors and stairs are essential. This program also indicates the need for compact design to avoid excessive travel time between rooms. The lower portion of the plan is at ground level; the upper portion is one half story higher. Below the upper level are additional classrooms and the administrative offices.

This plan of the Concord-Carlisle Regional High School, Concord, Mass. (Fig. 51), gives an indication of the variation in sizes of rooms needed to support a modern comprehensive program. Adaptation of room sizes to the needs of the class ensures maximum use of space. Grouping of students within classes is quite common and calls for the availability of small spaces where small groups from classes may meet informally. Likewise, there are many occasions when it is desirable to join two or more classes for a large group experience.

A small platform unit (Fig. 52) is recommended for elementary classrooms. It is portable and designed in four sections. The sections may be used together or separately for a variety of educational activities. This portable unit keeps the floor area flexible, whereas a permanent built-in platform limits the use of a section of the classroom.

Classroom Facilities

Modern teaching procedures require more complex classroom facilities than were considered necessary in the past. Provision should be

Fig. 49

- LARGE GROUP FACILITIES

Fig. 51 Warren H. Ashley, Architect

made for books, audio-visual equipment, recorders, television, tack space, and writing surfaces.

Many communities are building a self-contained classroom in elementary schools. This room requires facilities for teaching various subjects, such as English, mathematics, reading, arts and crafts, music, social studies, and science. This area is used exclusively by one group of pupils. Other schools provide certain facilities in special areas for use by numerous classroom groups. This design, however, may limit the program because it becomes necessary for groups to conform to a time schedule.

The elementary classroom will require storage for such items as science projects and equipment, reference books, paints, paper, posters, maps, globes, coats, boots, audio-visual equipment, records, lunches, and small playground equipment. For kindergarten and primary grades, toilets and coat storage areas located in or adjacent to the classroom are convenient for the teacher to assist the smaller children. Central toilet facilities should be provided for the intermediate grades and above. Drinking fountains in or adjacent to classrooms are desirable.

Several educational activities require such facilities as sink, counter work area, portable stage, hot and cold water, earth bed, and special furniture. Provision should be made for such items in accordance with the educational program when the building is planned.

Storage Needs in High School

1. Storage space for each group using the classroom should be provided with locks.
2. Storage is needed for the following items: supplies, such as paper and pencils; books and magazines; special equipment for the subject taught in the room (such as blueprints for mechanical drawing, globes and paperback reprints for social studies, and compasses and protractors for mathematics); and the teacher's coat and personal belongings, if not provided for elsewhere.
3. A standard storage closet, either of metal or wood, is recommended for all classrooms.

Storage Needs in High School

1. Storage space for each group using the classroom should be provided with locks.
2. Storage is needed for the following items: supplies, such as paper and pencils; books and magazines; special equipment for the subject taught in the room (such as blueprints for mechanical drawing, globes and paperback reprints for social studies, and compasses and protractors for mathematics); and the teacher's coat and personal belongings, if not provided for elsewhere.
3. A standard storage closet, either of metal or wood, is recommended for all classrooms.

Fig. 52

Fig. 53

ELEMENTARY AND SECONDARY SCHOOLS

Classrooms

Fig. 54

Fig. 55

Fig. 56

Chalkboard and Tackboard

1. The demands for chalkboard and tackboard will vary from subject to subject in the high school. Generally, English and mathematics require more chalkboard than do the social studies, which in turn require more tackboard. The minimum amount of chalkboard in any classroom should be 16 lin ft, and up to 48 lin ft could be used to advantage in many mathematics rooms. Approximately 16 to 32 lin ft of tackboard should be provided.

2. A display rail extending the entire length of the chalkboard is an essential teaching aid. Such a display rail should have hooks with clip fasteners. Provision might also be made for hanging pictures, maps, and charts on other walls of the room. Embedded picture molding should be installed on three walls at a suitable height.

3. Consider installing display cabinets to serve as classroom showcases.

Chalkboard installation is of great importance. For each room, consideration should be given to the type, amount, height, and necessary attachments. The recommended mounting

heights can be determined by reviewing the "working heights" chart (Table 6).

Chalkboard may be purchased in several different materials. Glass, slate, and porcelain-enamelled steel have proved satisfactory; however, asbestos-cement may be more economical. Avoid hardboard types. If the steel type is used, a three-coat finish will give more lasting results. The chalk tray should be designed for easy cleaning. A map rail is needed, complete with hooks and cork strip (Figs. 53 and 54).

Corkboard should be distributed throughout the school. Display of educational materials will support the educational program. Sixteen-foot sections are recommended for most classrooms and placed for easy viewing by students. The cork should be at least $\frac{1}{4}$ in. thick if staples or thumbtacks are used for mounting displays (Fig. 54).

A pegboard may be used to display three-dimensional objects on brackets, hooks, or shelves. The thickness of the board should be no less than $\frac{1}{4}$ in.; the tempered grade will give better service.

A high degree of flexibility in the use of wall

area can be obtained by building in adjustable hanging strips (Fig. 54).

Steel cabinet (Fig. 55) is a combination of teacher's wardrobe, file drawers, and a small cabinet for personal belongings. This unit should be equipped with a locking device. It can be built into a wall, set in a recess or corner of the classroom. A coat hanger rod and mirror should be included on the wardrobe side.

The unit in Fig. 56 may be used for storing large charts (24 by 48 in.), maps, graphs, large paper, paintings, projects, and audio-visual equipment. The lower half includes long, deep drawers and the top section provides a very flexible space with adjustable shelving. This unit will have its greatest use in elementary schools.

The storage unit in Fig. 57 serves also as a work counter and sink. The height is determined by the size of students. The sliding doors are safer and need less maintenance than swinging doors. The top and splashboard should be a durable plastic.

Figure 58 shows shelving or base cabinets along a window wall. The storage unit makes

* Recessed at baseboard height.

Fig. 57

good use of this area and provides counter space for plants and displays. The units may be prefabricated or custom built.

Working Heights for Students

Table 6 can be used as a general guide to acceptable working heights for elementary and junior and senior high school children. There is a large variation in the size of children within a particular classroom group and in various geographical sections of the country. The architect should obtain the median child height in the particular community and select minimum, optimum, or maximum heights as indicated.

MULTIPURPOSE ROOMS

The layout in Fig. 59 was designed for a small high school. As the student enrollments increase and additional classrooms are built, the stage will be removed and this area converted to dining. The room is located at the main entrance to the building, with a combined corridor and lounge. The chair and table storage is well placed with direct access to the

ELEMENTARY AND SECONDARY SCHOOLS

Multipurpose Rooms

service entrance. The room is opened up to the two wide corridors—an arrangement that permits overflow seating during special assemblies or public performances. The openings can be closed with drapes when desired. The openness reduces traffic congestion and discipline problems.

This cafeteria-assembly room (Fig. 60) is opened up on two sides, with the kitchen at one end. Overflow seating is available on the corridor side. The plan provides space for an adequate program within a limited budget.

The following information and drawings are primarily concerned with large areas in school buildings which are designed and equipped for two or more group activities. The most frequently used room combinations include assembly-cafeteria, assembly-cafeteria-gymnasium, assembly-gymnasium, and a student activity area where many small learning centers may operate at one time.

Assembly-Cafeteria

The assembly-cafeteria combination is popular because the room can be designed with a pleasing environment for both eating and assembly. This type of room is also more adaptable to scheduling without limiting other phases of the educational program.

The room should be furnished with tables that can be quickly moved into a nearby storage area. A large portable folding unit containing table and benches has proved satisfactory for elementary schools. Tables that fold into the wall are also available. Many high schools prefer the smaller folding table and stacking chairs, which permit a more informal and flexible arrangement.

This type of room should have a stage, stage curtain, backdrops, and adequate lighting for dramatic presentations.

Student traffic flow in this area should be planned. Minimum cross traffic is essential during the lunch period when children are carrying food. During student assembly periods good circulation may reduce discipline problems.

Assembly-Cafeteria-Gymnasium

The assembly-cafeteria-gymnasium combination can be found in schools where limited funds are available. This arrangement may seriously curtail the educational program. The time necessary to set up the cafeteria furniture, feed the children, clean the room, and remove the cafeteria furniture will consume a large portion of the school day. The remaining time available for physical and assembly activities may be insufficient for a good program. It is also difficult for the architect to design a room in which the atmosphere is conducive to dining, physical education, and assembly productions.

Assembly-Gymnasium

The assembly-gymnasium combination is a possible solution to seating the total student enrollment when a small or no auditorium is available. This area should be designed with a stage that can also be used for physical activity. Storage space will be needed for chairs, gymnasium equipment, and stage equipment. Acoustics, lighting, ventilation, and traffic flow should be adequate for assembly and physical education. This arrangement is not considered as satisfactory as the assembly-cafeteria combination.

Adequate chair storage is provided in this cafeteria-assembly combination (Fig. 61) for an

Fig. 58

Fig. 59 Chapman and Leffler, Architects

Fig. 60 Chapman and Leffler, Architects

ELEMENTARY AND SECONDARY SCHOOLS

Multipurpose Rooms; Student Lockers

elementary school. The low display can be moved and overflow seating is available in the lobby corridor. Public toilets are well placed. The stage has outside and inside access independent of the main room. The music room and the stagecraft area provide adequate space for school or public performance preparation.

The gymnasium-assembly combination shown in Fig. 62 provides chair storage, gymnasium storage, stage, and exercise rooms. The large gymnasium has a large folding door which provides two teacher stations. The stage can be divided with a folding door to provide two more stations. Access to shower rooms is on either side of the stage, and the stage can be entered from the corridor on either side. Folding bleachers close the proscenium opening when the stage is used as exercise rooms.

STUDENT LOCKERS

Many different solutions have been developed to solve the problem of storing coats and personal belongings of students. In the elementary school, proximity to the homeroom for ease

Fig. 63

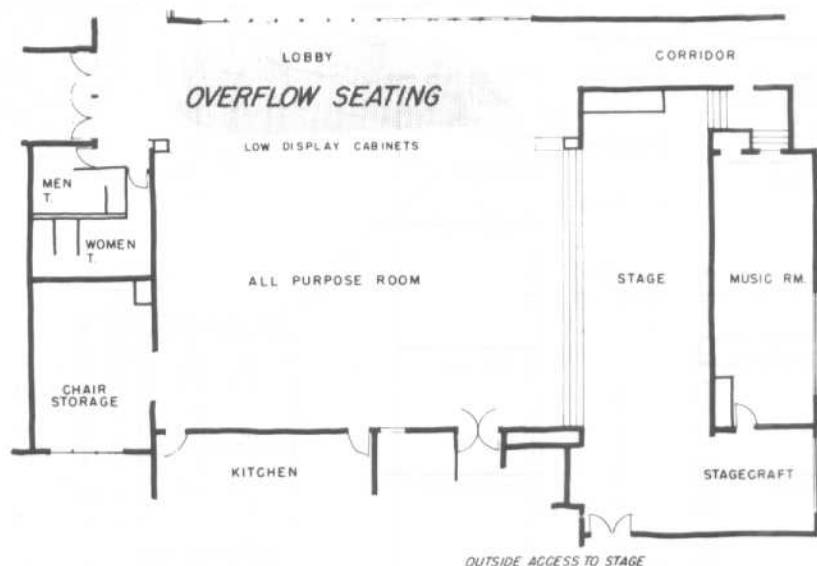

Fig. 61 Chapman and Leffler, Architects

of teacher supervision is important. Lockers in the high school should be located for easy access between periods. Circulation in the locker areas should be sufficiently adequate to prevent congestion. It is generally necessary to provide arrangements whereby students may lock up personal belongings and books. Most high schools also provide lockers with locks for coats. However, others have been successful in providing small security lockers and open coat racks.

Figure 63 shows one way of storing coats, boots, and small personal articles in a four-classroom unit of an elementary school. Ventilation can be provided economically. This type of open cubicle should have permanently attached coat hangers. The boot rack should be constructed of materials resistant to water and dirt.

Another way of storing coats is within a classroom (Fig. 64), where the storage area serves also for passage of pupils. The area is convenient for teacher supervision. The coat and toilet areas for all four classrooms are located together, permitting economical utilities.

Fig. 62

Fig. 64

ELEMENTARY AND SECONDARY SCHOOLS

Student Lockers

A. G. Odell, Jr. and Associates, Architects

Fig. 65

Lockers may be concentrated in several conveniently located areas (Fig. 65). These areas are completely open and the wide spaces between rows provide comfortable circulation. This type of locker arrangement eliminates congestion in corridors and frees corridor walls for display and vision panels. As locker alcoves are difficult to supervise, it is essential to provide complete circulation around the entire space.

Another way of treating locker installation in a high school is shown in Fig. 66. The lockers have been concentrated in two areas near the entrance and student center. The areas have been left open with ample space for comfortable circulation. Restrooms are adjacent to the locker area, which may reduce corridor traffic and save student time. Each student is assigned a security locker for books and personal items. Coats and boots are stored in open coat racks.

Coat storage (Fig. 67) in a classroom can be closed off by means of a folding partition. This arrangement gives students easy access to wraps. The area is convenient to supervise and the classroom area provides space for dressing

and circulation. Mechanical ventilation is needed to dry wet clothing and avoid odors. However, this plan uses up wall space that might better be used for educational purposes.

The type of storage shown in Fig. 68 is usually found in elementary schools where open cubicles are desirable. These units are located on the classroom side of a single-loaded corridor for convenient supervision. The walls have been splayed to relieve corridor congestion during the arrival and dismissal of children. The splayed wall also provides a recess for the classroom door.

In Fig. 69, panels fold to provide the doors on the wardrobe. Mechanical ventilation is essential. The large amount of wall area used by this system may introduce serious handi-

COAT RACK

SECURITY LOCKERS

SECTION

Fig. 67

ELEVATION

SECTION

Fig. 66 Chapman and Leffler, Architects

ELEMENTARY AND SECONDARY SCHOOLS

Student Lockers

caps in the use of the room for teaching purposes.

The locker unit (Fig. 70) is used as a space saver. These units give an economical approach to coat storage. Each student may be assigned a personal locker for books and small personal belongings. The coats are hung on

permanently attached hangers. This unit permits natural air circulation for drying coats and is convenient to supervise.

The detail in Fig. 71 shows the recessed corridor lockers, which are seen below in elevation (Fig. 72). The ceramic tile base is used to simplify floor maintenance. The ceiling is

Fig. 68

Fig. 69

Fig. 70

Fig. 71

Fig. 72

ELEMENTARY AND SECONDARY SCHOOLS

Student Lockers; Language Laboratory; Science Facilities

furred down to eliminate the accumulation of dust and trash on top of the lockers. These units can be ventilated by pulling air through lower front vents and into the plenum above.

LANGUAGE LABORATORY

The language laboratory provides a place where pupils can listen to recordings in a foreign language, make their own recordings, practice speaking a foreign language in private, and carry out drill exercises.

It should have students' booths constructed of sound-absorbent material, approximately 30 or 36 in. wide, 36 in. deep, 54 in. high. These should face the teacher. The top front half should have a see-through glass panel so that the student can see the teacher, and so that the laboratory can easily be adapted for audio-visual aids. The back wall and ceiling should be treated with acoustical or sound-absorbent materials (see Fig. 73).

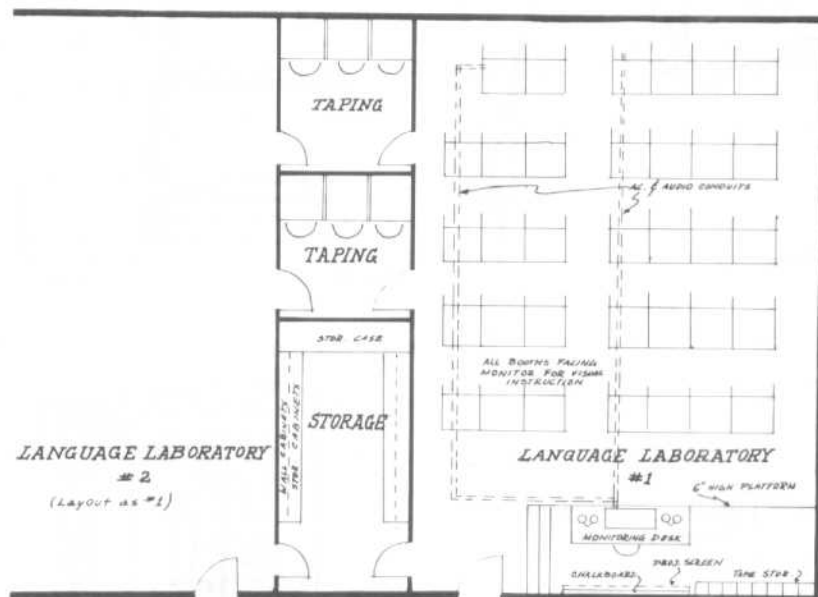

Fig. 73

Booths should be equipped with headphones, microphones attached to a flexible gooseneck stand, magnetic disc or tape recorder, and a control panel with switches for selecting balance and volume. There should be a monitor jack on the same panel.

At the front of the room, the teacher's area should have a platform at least 6 in. high in order to raise the level of vision into the student booths. The master unit should accommodate three channels for simultaneous programs and should also contain two dual-track tape recorders and two phonographs, four-speed. A small soundproof booth will be necessary to enable the teacher to make master tape recordings. A typewriter with international keyboard is needed.

Storage and small recording rooms should be separate.

SCIENCE FACILITIES

General Science Rooms and Biology Laboratories

General science rooms and biology laboratories should be located on the first floor, with windows facing south or southwest, a door opening into the preparation room, and a door opening onto the campus so that classes may study outdoors without passing through the building (see Fig. 74).

Activities include lectures, demonstrations, viewing projected materials, individual and group study, writing, and experimentation with animals and plants.

The front wall should be equipped along its entire length with chalkboard, the center section of which should be raisable. There should be a display rail over everything except the raisable section of board. Provision should be made for a projection screen at the front

shelves are desirable. Instructor's demonstration desk should be equipped with hot and cold water, duplex ac receptacle, soapstone sink, upright rods with clamps and wood crossbar, and double gas cock. Also needed are two student biology desks with one cupboard and two book compartments; chairs, mock-up table; herbarium, aquariums; projection screen; microscopes; models, charts; dissecting trays; specimens; portable germinating bed; terrarium; microprojectors; three sinks with towels and soap dispensers; experiment sheet filing cabinet near tackboard; first-aid cabinet; fire extinguisher.

Electric outlets should be located on each of the walls. If the entire class uses electrically

Fig. 74

lighted microscopes, tables will need electric outlets. Sinks and outlets for gas and electricity are needed in counters.

Storage and Preparation Rooms

Storage and preparation rooms should be adjacent to general science and biology. These rooms are used for teacher preparation, storage of bulk supplies, conferences and offices.

This area should be lined with storage spaces for materials and equipment of various sizes. There should be provision for teachers' records and professional books. Room should be outfitted with a sink and gas and electric outlets. Access windows should open into the laboratories.

Storage provision should be made for equipment used in general science and biology. A storage bin, made up of many small drawers, each measuring approximately 4 by 4 in., should be included for efficient storage of small items of equipment. Also needed are desks and chairs; preparation table on wheels; preparation table with drawers; standing storage cabinet for charts; cabinet with slides; bookcase; shelving to ceiling; sink with hot and cold water; gas and electric outlets.

of the room. Corkboard 4-ft wide should cover the entire width of the back wall above the wainscoting. It is suggested that counters be installed along two sides of the room, one being the window side. Such counters should include several sinks and outlets for gas and electricity.

All laboratory furniture should be acid-resistant and easy to wash and clean. Equipment includes a display case for biological specimens that opens to the corridor from within the room; teacher's combination wardrobe and closet; legal-size file with lock; storage areas for notebooks, aprons, microscopes, instruments, specimens, biologicals, pupil projects, microprojector, and books. A storage cabinet at counter height might be installed along window wall. Locked sliding door extending the entire length of the storage cabinet and metal

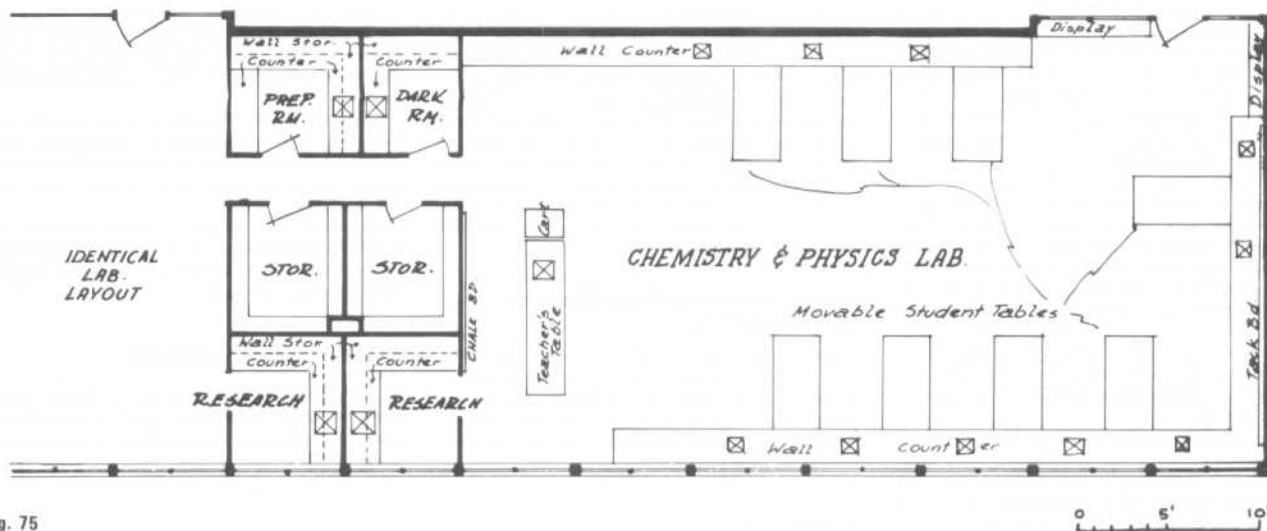

Fig. 75

Plant and Animal Room

The plant and animal room should be located adjacent to the biology laboratory, possibly adjacent to a biology storeroom. Easy access to the outdoors is desirable.

Southern exposure is desirable. This area should be arranged like a greenhouse, with sanitary finishes and a concrete floor with drain so that the room can be hosed down. In addition to sunlight, the plant room will require special ventilation and heating so that it does not get cold overnight. Special heating, thermostatically controlled and separate from other parts of the building, should ensure even heating during weekends and holiday periods.

Equipment includes table and racks for plants; growing beds on wheeled tables; animal cages; feeding trays; storage for food, tools, equipment; sink with hot and cold water; hose; pails; hand garden tools; bins for loam, sand, and peat moss.

Chemistry Laboratories

Chemistry laboratories should be readily accessible from individual research and prepara-

tion rooms (see Fig. 75). Laboratory activities include demonstrations, individual and group study and experimentation, writing, viewing projected materials, and lectures.

At a comfortable height there should be student stations for 24 students, consisting of tables with large free working area and all services available: ac and dc variable voltage should be provided. The front wall should be equipped for its entire length with a chalkboard, the center section of which should be raisable. There should be a display rail over all but the raisable section of board. On the back wall above the wainscoting level, there should be some corkboard and pegboard with hardware. A fume hood, accessible from three sides, should be provided.

One end of the room should contain the teacher's desk and a demonstration area with a 5-in.-high dais for demonstration. Demonstration table should have a stone top, spotlight lighting, and a roll-away extension. All services should be provided for the demonstration, including variable ac and dc voltage. Sound cable should be installed in the floor for projection purposes. Provision should be made for darkening the room.

Special attention should be given to the furniture for this space. As a minimum, it should be acid- and base-resistant and easy to wash and clean. It should include tablet armchairs; teacher's combination wardrobe and closet; acid-proof sinks with dilution tank; storage for chemical supplies; storage space in laboratory tables; normal chemistry laboratory equipment for semi-micro techniques; salt and solution cabinets; three rolling tables to service tables; standard reagent storage area; locked cupboards for delicate instruments and dangerous chemicals; fire extinguishers and first-aid kits; storage for notebooks and aprons; experiment-sheet filing cabinet; charts and models; projection screen.

Physics Laboratories

Physics laboratories are used for lectures, demonstrations, viewing projected material, individual and group study, writing, individual and group experimentation (see Fig. 76).

Around the room on three sides at a comfortable height (higher than the ordinary table) should be a work station for each student,

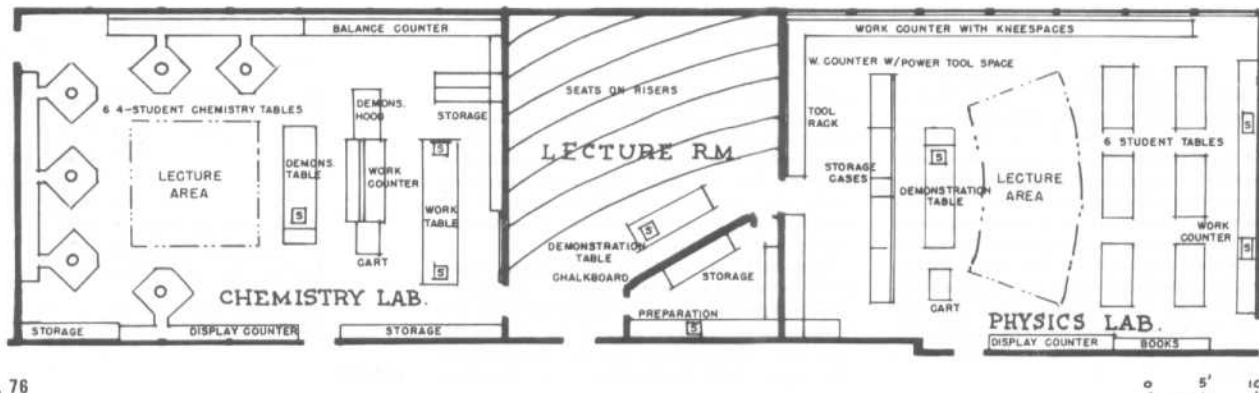

Fig. 76

ELEMENTARY AND SECONDARY SCHOOLS

Science Facilities

consisting of a table with a large free working area and all services available; ac and dc variable voltage should be provided to all stations; voltage should be supplied by several portable voltage-regulating units. Sinks should be available. Some attention should be given to permanent or semipermanent laboratory stands for rigging equipment.

One end of the room should contain the teacher's desk and a demonstration area with a 5-in.-high dais for the demonstration table. The demonstration table should have a stone top, spotlight lighting, and a roll-away extension. All services should be available. Down-draft ventilator is suggested, but it should be positioned so as to give as much unobstructed broad area on table surface as possible. It should not be centrally placed. Tablet armchairs should be placed in front of the demonstration desk.

The room should have as much chalkboard space as possible, since chalkboard work with problems constitutes a considerable part of class time. Ample corkboard space and some pegboard with hardware are needed.

Attention should be given to darkening the room properly. This is important for the projection of movies and slides, as well as for demonstrations that require a darkened room, and for some laboratory work such as photometry. Sound cable should be installed for projection purposes and antenna facilities for television and radio reception. There should be central control of lighting.

Doors should open into the front of the laboratory. An open-joint ceiling has the advantage of permitting hanging of apparatus. A ceiling hook capable of holding a $\frac{1}{2}$ -ton load should be provided.

One of the main problems for the physics area will be provision of adequate storage space for a vast amount of demonstration equipment and specialized scientific apparatus. Storage space with glass doors for visibility, bookshelves for a reference library, and a cabinet for notebooks should be provided.

Preparation and Storage Rooms for Chemistry and Physics Laboratories

Preparation and storage rooms should be adjacent to laboratories, with a door leading to corridor and laboratory. They are used for teacher preparation, storage of bulk supplies, and conferences.

The area should be lined with storage spaces for materials and equipment of various sizes (in chemistry, glass tubing, long items, tall items). All shelves should have lips to prevent slippage, and should be built so that the floor supports the weight, unless the storage area is small and specifically designated for light items.

Chemistry Open shelving of cabinets is favored for storage of bulk chemicals. Special transite-lined volatile closets vented to the outside for volatile reagents, acids, and alkalis should be provided, along with provisions for the teacher's records and professional books. The room should be outfitted with sink and gas and electric outlets. It should also have storage provision for all equipment, a preparation table large enough for six analytical balances, adequate work space for preparation, special storage for charts so that they are kept flat, not rolled, desks and chairs, preparation table on wheels, ladders with rail, and a bookcase.

Physics A storage bin made up of many small drawers measuring approximately 4 by 4 in. for efficient storage of small items of equipment is suggested. Electric outlets similar to those provided in demonstration table, as well as plentiful 110-V ac outlets, and adequate lighting should be provided, as well as ladders with rail to reach stored items, and a workbench and sink with drainboard along one side, to repair and set up equipment. The bench should be rugged enough to take considerable hammering.

Individual Research and Project Rooms for Chemistry and Physics

Research and project rooms should be adjacent to chemistry and physics laboratories and separated from them by half-glass partitions. They are used for individual and small group study and experimentation, instruction, and research. (See Fig. 89)

Science Shop

The science shop and the darkroom may be built as a unit and placed back to back between the corridor and the window side. The project room should be located on the window side and have a door opening into a laboratory. A glass wall will enable the teacher to keep the area under observation.

The science shop is used for individual work in making and repairing instruments and equipment.

It should have a workbench and sink along one side of the room. The bench, for repair and setting up of equipment, should be rugged enough for metalworking.

The furniture and equipment should include equipment drawers, work counter, drill press, small metalworking lathe, some storage shelves for reference books, tool storage, sink, and ample space for electrical equipment. Electric outlets similar to those provided in the demonstration desk should be available, as well as 110-V ac outlets.

Darkroom

The darkroom could be placed back to back with the science shop and located on the corridor side with the door opening into the corridor.

It is used for developing film and the storage of darkroom materials and reagents, mounting equipment, and the like.

A vestibule and two-door entrance will prevent light from entering. The area could be divided into a small room near the entrance for weighing and mixing chemicals and a larger room toward the rear for developing and printing.

A counter should be constructed along three sides of the room, 34 to 36 in. high and 24 in. wide. There should be a large chemical-resistant open sink, 24 by 30 in. and 18 in. deep; and a wet bench, attached at either end, draining into the sink. The sink must have both hot and cold water. Stainless-steel surfaces are recommended; finishes must be easily cleaned and stain-resistant.

Shelves 12 in. apart and 10 in. deep should be constructed above the counter. Storage in standard darkroom style should provide tray and chemical storage as well as shelves for dry stock. Since the room will be used for dry work, such as spectroscopy, provision

should be made for sit-down as well as stand-up dry work. Walls should be finished a flat green for eye ease. Serious attention must be given to ensure adequate ventilation of this room.

Furniture and equipment will include re-touching table; developing; enlarging, and printing equipment; dryer; print washer; trays; paper cutter; hot plate; safe lights; timer; fire extinguisher; clock.

At least four double electric outlets are needed at the counter. There must be sufficient plugs for all appliances, conveniently placed near all work positions.

AUXILIARY SCIENCE FACILITIES

Special science facilities like animal rooms, greenhouses, vivariums, and planetariums are not exclusively part of large science complexes. Sometimes a given instructor will have

Fig. 77

Fig. 78

ELEMENTARY AND SECONDARY SCHOOLS

Science Facilities

Fig. 79

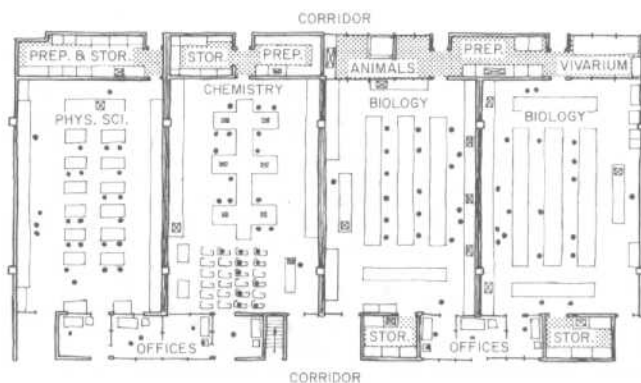

Fig. 91

Fig. 94

ELEMENTARY AND SECONDARY SCHOOLS

Science Facilities; Arts

a special interest, or a local business group or community effort will focus on funding such added programs. As a result, such spaces often get extra special attention in their development

Fig. 95

from everyone, demand research, turn out to be topnotch, and really excite the students.

Figures 95-98 exemplify a vivarium and a planetarium, neither of which requires much area, but both entail special equipment, special care and know-how to construct and operate. The vivarium shown is located in a high school suite between two biology laboratories, backs up to a preparation room, and fronts, through a glass wall, to a main circulation corridor. Skylit, its setting of sun, animals, plants, and water brings nature right into the everyday action of the school.

Fig. 96

Planetariums, as very special spaces, can be accommodated within a building or developed as a satellite facility, as the one example indicates, being built from prefabricated manufactured parts. Many specially motivated students, particular parent and community pride, and unique accomplishment have derived from having such bonus facilities.

ARTS

Working surface, and lots of it, by way of counters and tables is a basic requirement, as is wall space for display and storage cabinetry. Figure 99 shows a well-equipped, typical general art room with sinks (X squares) in the perimeter counterwork, allowing flexibility for various table and desk combinations. Figure 100 shows a larger art suite, with no windows and all kinds of wall space, artificially well lit, with a storage core and peninsula sinks, but otherwise open, flexible space utilizing 7-ft-high storage units as dividers of functions.

Corridors flank the art suite shown in Figure 101 that develops as an interior core unit related to typical classrooms along the corridors. Glass over the work counters allows the creative activities to be seen from the corridors, showcasing an attractive interest center.

Where storage requirements are so unique and stringent, and working techniques so important in the work done, certain special details and ideas develop as useful and practical. Some of these are noted here. Figure 102 shows a room well equipped with all kinds of cabinets and counters, plus one bonus extra, that of wires stretched across to hang prints on to dry. Figure 103 shows a clay wedging board, useful for working in clay. Figure 104 is a common available light track, allowing feature lighting fixtures anywhere. Figure 105 shows a way of storing fabric for use in silk-screen work. A spare roll is kept forward, and the working roll is looped around and then fed under a cutting gate board. Figure 106 shows movable platforms set on lockable casters to serve as a model stand.

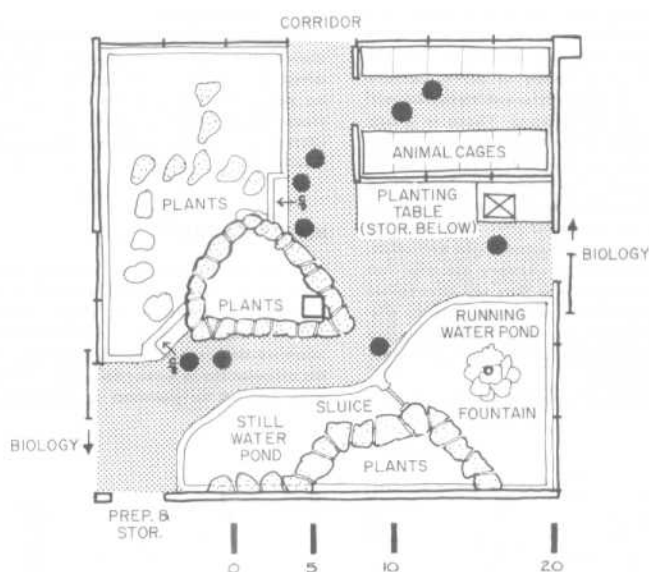

Fig. 97

Fig. 98

ELEMENTARY AND SECONDARY SCHOOLS

Arts; Music Facilities

Displaying art work itself becomes a creative and practical challenge. Ample tack surface should be available on the wall. Display devices can be hung from the ceiling, developed as free-standing kiosks, or used in other constructions, even in front of windows to set ceramic pieces on. The art room should be an exciting place to be and to work, amid work that has been done to encourage comparison and increasing quality. Finishes should be practical and spartan, for it is a laboratory to work in with freedom to explore and, if necessary, to be messy.

Arts and Crafts Rooms

Arts and crafts rooms should be located near auditorium stage, stagecraft area, homemaking, industrial arts, dramatic, and music rooms. Location should facilitate delivery of supplies. They should have an outside door, for use when holding classes outdoors, and good natural lighting.

The space should be arranged with sufficient imagination so that it is flexible and allows the teacher to vary the curriculum from year to year. The program involves the use of a number of media. Rooms, therefore, should be conceived of as a series of work centers in which activities with different kinds of materials can be carried forward. There is much need for display space for finished work. Walls should be of material that will receive thumbtacks, to eliminate the need for broken-up wall panels and bulletin board. Avoid breaking up wall spaces uneconomically; keep display areas large and simple. Phones, light switches, thermostats, and other necessary electric outlets should be placed where they are accessible but do not interfere with otherwise usable display spaces. Windows should provide adequate light and be high enough for storage and counter space underneath.

Ceilings and/or walls should be acoustically

treated. It is preferable to have a vinyl asbestos floor in the general art area; in the ceramics area terrazzo or hardened concrete floor is suggested. Finishes should be easily washed and maintained, and resistant to oils and heat. A chalkboard should be placed where it can be seen easily but where it will not produce reflections or shine. It could be incorporated in a cabinet of vertical sliding balanced sections to include two chalkboards, one corkboard, and one projection screen. A bulletin board and opaque drapes or light-tight venetian blinds for darkening the room are also necessary.

Suitable lighting is needed to ensure effective color rendering on dark days and in the evening. Semi-indirect lighting with daylight bulbs is recommended. If the room is located on the ground floor, it will need protection against ground glare in lower sash of windows. Double sinks with hot and cold water; drinking fountain outlet; gas outlets; enough electric outlets around room for projectors and spotlights; and heating by ceiling or floor radiation to save floor and wall space, or at least a minimum allocation of space to this utility, are also recommended.

Room for bulk storage and storage of papers, illustrative materials, models, cardboard, finished and unfinished projects will have to be supplied. The area will require much protection against fire. Shelving, suspension facilities, and bins should be arranged for great flexibility.

MUSIC FACILITIES

The music program is usually divided into four parts: instrumental activities; choral activities; classes in music theory, music appreciation, and voice; and correlated activities, such as drama and opera projects. Good traffic circulation is essential. Instrument storage area should be planned so that students can

circulate easily to collect their instruments, attend class, and return instruments for storage. It should be convenient to move large instruments to buses, stage, and playing field.

The size, shape, and construction material are important factors to consider in planning and designing music facilities for the best sound control possible. The architect should aim for rooms that have optimum reverberation time, even distribution of sound, and freedom from undesirable absorption at certain pitches. Nevertheless, the reverberation period must not be reduced below the point mandatory for correct brilliance of tone. Nonparallel walls or splayed walls and ceilings should be considered; soundproof walls and doors are desirable. Acoustic ceilings and walls should be carefully designed to ensure satisfactory conditions within each room. Storage areas should serve as sound-transmission buffer areas to keep interference between music rooms at a minimum. It is recommended that a competent sound engineer be consulted in preliminary planning stages.

Music Classroom

The music classroom should be part of the music suite and readily accessible to corridor and office (see Fig. 107).

It is used for class instruction, choral work, and as a dressing room for large groups.

It should have sound-tight doors, natural lighting, lavatory, and a dressing table. A chalkboard ruled for music, bulletin board, piano, and tablet armchairs will be needed.

Provision should be made for projection, television, and a high-fidelity sound system.

Choral Room

The choral room should be near the rear of the auditorium stage so that choral groups can move easily onto stage for performances.

Fig. 99

Fig. 100

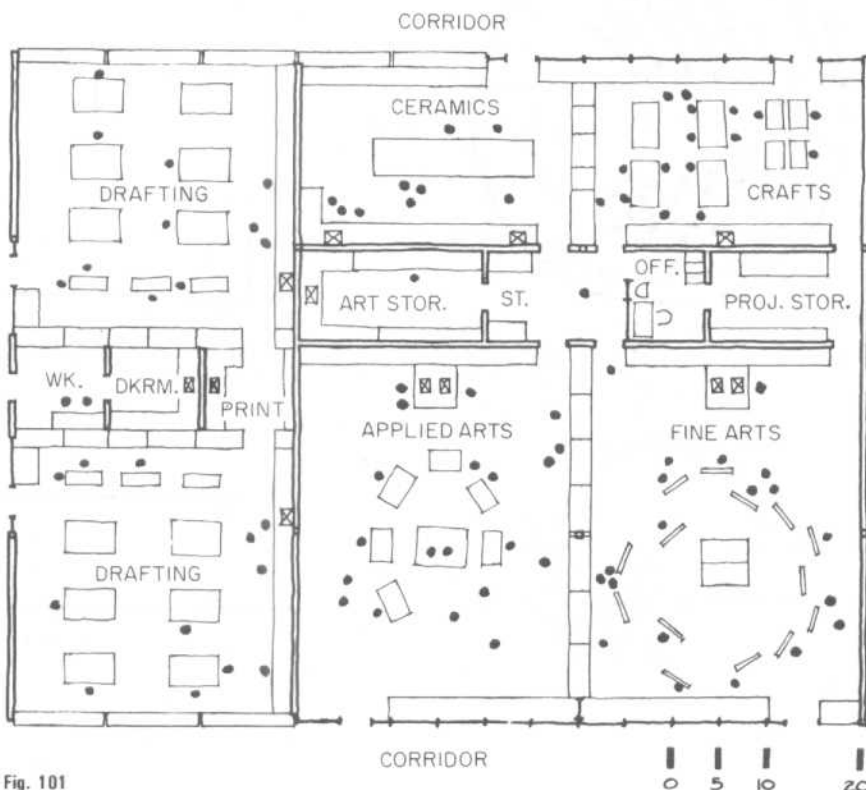

Fig. 101

ELEMENTARY AND SECONDARY SCHOOLS

Music Facilities

Fig. 102

It is used for boys' and girls' glee clubs and mixed chorus.

The room should have a flat floor and 6-ft-wide doors so that a piano can be moved in and out. It may be rounded at rear. A chalkboard with music ruling on part of it, a pull-type screen over the chalkboard, and a bulletin board are recommended.

Furniture and equipment include movable seats of the drop-arm type, conductor's platform, record player, tape recorder, storage for records and sheet music, piano, television set, portable risers, and clock.

Room should have natural lighting, ventilation, soundproofing, provisions for music recording and reproduction, two built-in 12-in. speakers with proper connection for either record player or microphone plug-in to serve for broadcasting over school public-address system.

Instrumental Music Room

The instrumental music room should be near the rear of the auditorium so that the band can move instruments easily onto the stage, near an outdoor entrance so that the band can

have access to the field without going through the building, and near practice rooms.

It is used for band, orchestra, brass and woodwind ensemble, chamber music groups, and sectional rehearsals.

The space should have a flat floor and doors 6 ft wide to move piano in and out. Doors should be soundproofed. Storage space in back and sides of room, chalkboard with music ruling on part of it, pull-type screen over chalkboard, and bulletin board are suggested.

Furniture and equipment include movable seats, conductor's platform, record player, tape recorder, piano, television set, music stands, small sink, counters for books with music slots below counters, storage for records and musical scores of various size, portable risers, and clock.

The room should have special soundproofing; natural lighting and ventilation, if possible; provision for music recording and reproduction; two built-in 12-in. speakers with proper connection for either record player or microphone plug-in to serve for broadcasting over school public-address system; outlets for 16-mm sound motion picture projector. Reproduction in music rooms requires high-fidelity equipment.

CLAY WEDGING BOARD

Fig. 103

Fig. 104

Practice Rooms

Practice rooms should be near band and orchestra room. They are used for practicing and individual instruction.

They may serve as music listening rooms. Soundproof doors, and soundproof windows into corridor, are necessary for supervision.

Equipment includes music rack, small table, music lamp, chairs, clock, and counter for instruments and books. It may have a piano and phonograph.

Electric outlets and artificial lighting are needed. Special acoustical treatment is necessary to prevent interference between rooms and with other areas and to deaden reverberation. Special attention should be paid to mechanical ventilation.

Fig. 105

ELEMENTARY AND SECONDARY SCHOOLS

Music Facilities

Fig. 106

Fig. 107

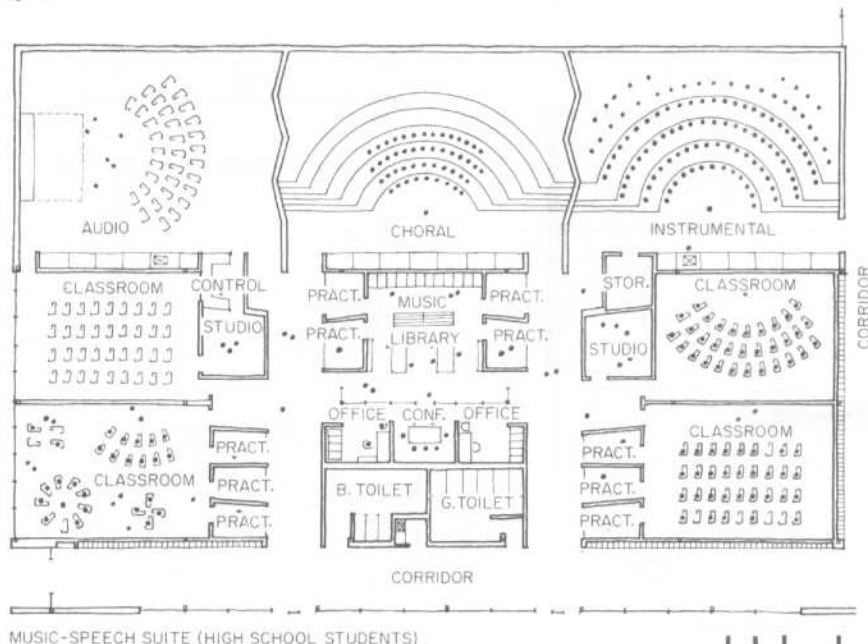

Fig. 108

Music Office and Library

The music office and library should be between the choral and instrumental rooms. It should provide good supervision of spaces in music area.

It is used as an office—for teacher conference, teacher preparation, and keeping records—and a library—for research, reading, studying, and storage of music.

Furniture and equipment include teachers' desks and chairs; wardrobe space; conference table; work counter; adjustable shelves on

walls; bookcase; cabinet for records; typewriter and stand; phonograph; radio; and playback machines.

Music Storage Room

The music storage room should provide safe, sanitary protection against robe and uniform destruction. Cabinets, 3 ft deep, 30 ft long, equipped with racks and hangers and space above for hats and lockers, for special band equipment such as flags and batons, and with lockable sliding doors are desirable.

Instruments need maximum care and preservation from damage. Adjustable shelving must vary according to instrument sizes. Roll-away racks for bulky instruments are needed. Smaller instruments are best cared for in cabinets. Other provisions include lockers with master-keyed padlocks, student benches, record cabinet, music filing cabinet, piano dolly, and music stands. If possible, a small area for instrument maintenance should be provided: sink with hot and cold water, floor drain, shelves, workbench, gas outlet for Bunsen burner, and counter for instrument repair.

A complete music suite is shown in Fig. 108 accommodating all the functions with related storage. Tiers in the choral and instrumental rooms are often built-up from the flat, main-level structural floor. Figures 109 to 111 show a practice room noted for proper sound isolation and equipped for double duty as a theater dressing room since music facilities are commonly related to the auditorium facilities for instrument storage.

Figure 112 shows in more detail an instrument rehearsal room, with student stations shown as dots, and practice rooms across a typical circulation corridor; a very typical, basic situation allowing free use of the practice rooms and easy access to the small instrument

PLAN-MUSIC PRACTICE RM. W/MAKEUP CABINET WALL

ELEMENTARY AND SECONDARY SCHOOLS

Music Facilities

storage lockers along the corridor (see Fig. 113). Large instruments are stored in the rehearsal room in rolling racks (Fig. 114) to allow for their easy moving for away-from-home performances. In this scheme, the room steps down from the corridor, allowing the generation of adequate volume in the room without stepping the roof up. The front wall is made heavily absorbent to sound-simulate playing to an audience: the ceiling is 50 percent reflective and 50 percent absorbent so that one section of the room can hear the other.

Figure 115 shows a related reflected ceiling pattern, and Fig. 116 shows some details for "soft" and "hard" surfaces. Figure 117 is another convenient space saver.

Fig. 117

INDUSTRIAL AND VOCATIONAL FACILITIES

Industrial and vocational education are one and the same, "vocational" being the more current term and implying a more specialized education program designed to train a person for a vocation rather than simply acquainting him with a working knowledge of tools and their uses. Many schools extend their in-school education to cooperative programs with local industries, providing the student with actual on-the-job experience. Additionally, industry representatives counsel and work with the students in the school.

The industrial arts department should be isolated from quieter areas of building, with a service road provided nearby. There should be an outdoor shop area, if possible. Access to shower and locker facilities will be needed. All machines and equipment should be arranged so that a sequence of operations can be carried out with the greatest possible efficiency.

Special servicing requirements of materials, relationship to drives for automotive shops, noise levels, and kinds of functions performed

very realistically determine the relationship of the vocational education area to the total plan. Also, because the school's functions are essentially industrial in nature, related structural and enclosure systems are appropriately different from the more finished elements in the remainder of the school. One-story structures on grade are most common, though mezzanine space is often developed for storage or seminar use.

However, this does not mean that the spaces cannot be attractive in their own way. For it is most important to the student, and the relationship among all students, that no one is being discriminated against. All are being treated equally. And so in relating the vocational education units to the rest of the school, rather than being a separate or tail-end unit as it was so often in the past, it should be made as integral a part of the total school as possible, physically and philosophically.

Basically, the major elements of vocational education are specialty shops like woodworking, electrical, metals, auto, or combined general shops. Additionally, drafting rooms are common as well as supporting classrooms,

offices, and sometimes locker rooms. The layout of any shop should follow the logic of its equipment use and its relationship to electrical and mechanical services. Several things must be considered such as special code and safety concerns, good lighting, sawdust collecting systems, overhead hoist systems, exhaust ducts, and the ability to get large supplies in, out, and stored. It should also be realized that students are learning on the machines, and extra clearances should be allowed for joint teacher-learner use.

Figure 118 shows a layout of typical shop types with related spaces. Typically the class meets first in the classrooms, to learn principles, take certain tests, and put these into practice in the shop laboratories. In the diagram the dots represent students, the semi-circles group sink-wash units. Figure 119 shows a more comprehensive shop suite. Figure 120 is a section through a not unusual higher-ceiling shop area showing open-structure treatment, rooftop mechanical units, and the development of some double-deck space.

The specific equipment provided in any shop is determined by the client and by the various

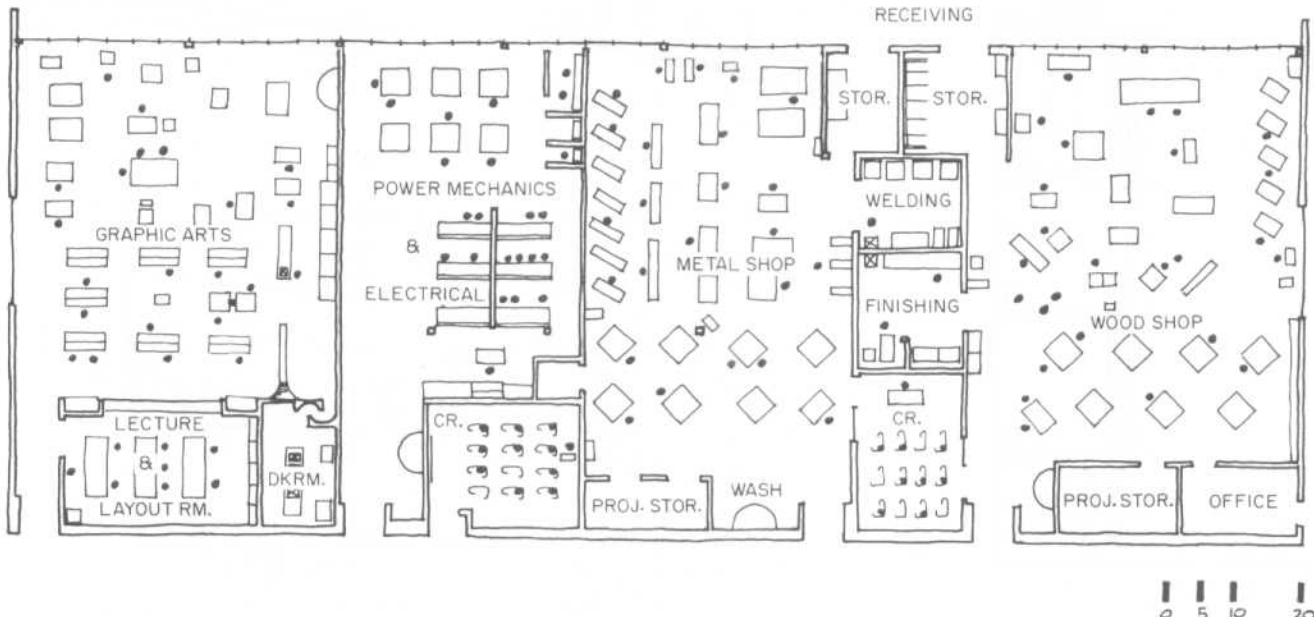

Fig. 118

ELEMENTARY AND SECONDARY SCHOOLS

Industrial and Vocational Facilities; Home Arts

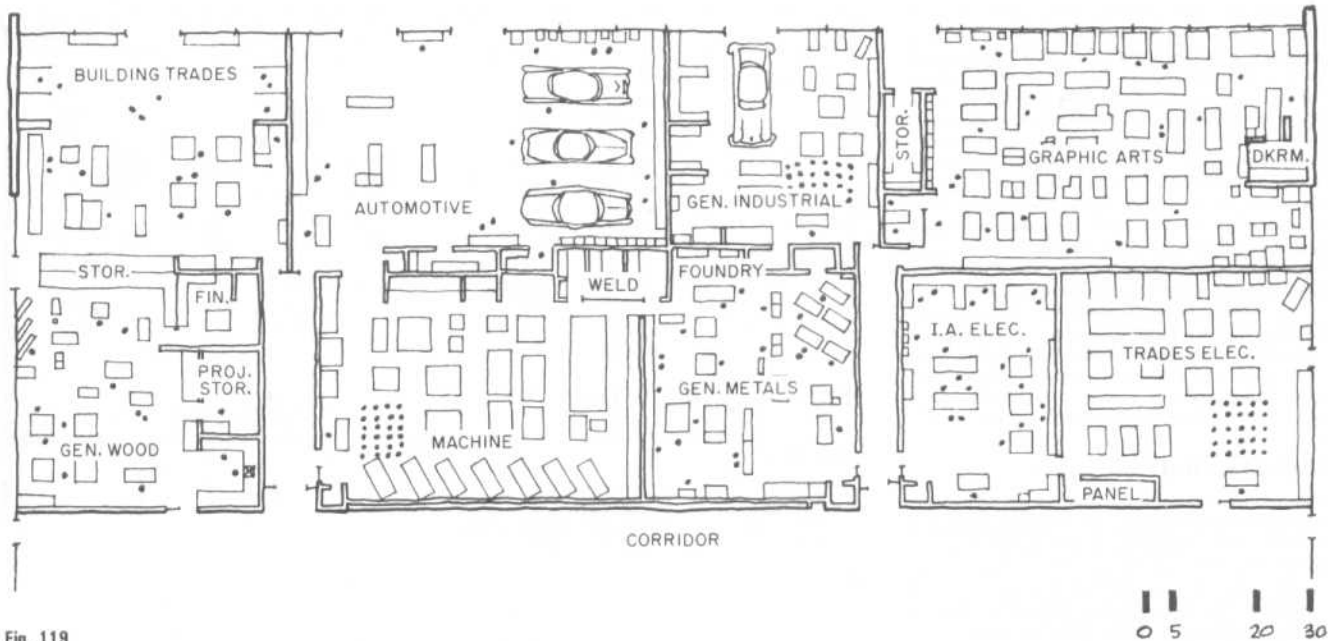

Fig. 119

Fig. 120

Fig. 121

requirements most states have. Sometimes the equipment itself is leased, another reason for the increasing preference for electrical service being fed down from the ceiling rather than up from the floor, allowing more flexibility. While most surfaces must be hard for maintenance reasons, some acoustic relief can be introduced by acoustic-absorbent mounted blocks in ceiling materials, roof decking, and high wall surfaces.

A sense of order should prevail in considering the equipment needs and the disposition of services to them, for a well-organized shop is itself a deterrent to accidents.

HOME ARTS

Home arts might be better called family-life education, for its purpose is to teach students about everyday living, home life, cooking, sewing, personal care, and caring for a home and family. It would be well if boys could participate more in the curriculum, and this might well be encouraged by a more central location of the facilities in the total plan and merchandising and refurbishing it in a less exclusively feminine way. For it should represent the feeling and purpose of the total home in the school; even outdoor patios might be included.

Facilities comprising a home arts program can range from a single laboratory space serving cooking and sewing classes to a full suite of spaces embracing these, and child development, cosmetology, living-dining, and support-

ive classroom areas. The various examples shown here illustrate program emphasis, and the many combinations possible, the relationships of one space to another, and the apparent flow of activity functions. Obviously, the larger the facility, the more difficult to avoid an institutionalized character. But it should be realized that certain of these programs are directed toward institutional vocational education, others toward homemakers.

Food Laboratories

The food laboratories may be divided into cooking area, freezing area, laundry, wall storage (for tote drawers, staples, cleaning supplies, and books), and classroom area large enough to accommodate movable desk chairs for students. Grease-resistant asphalt tile or linoleum flooring is necessary. Folding doors or screens could be used to separate areas.

Unit kitchens should contain equipment for about four students and include stoves, double sinks, counter space, and storage cupboards above and below the counters. Enameled-steel upper and lower cabinets with back splashes which are molded into a curved surface rather than joined together with stainless-steel strips are suggested. Movable supply wagons made of materials similar to those of other kitchen equipment can be built to fit into recessed space under the counter surface. Allowance must be made on the window wall for access to windows. Counters should be made of a durable material with two areas large enough

ELEMENTARY AND SECONDARY SCHOOLS

Home Arts; Food Service

to place two boards 16 by 20 in. next to each other so that two students can work side by side at each area. These should not be located at a corner since this does not allow space for two pupils to stand and work together. Minimum desirable length of counter per pupil is 30 in. If counter width is 24 in., minimum desirable size of one unit kitchen should be 11 by 9 ft, or 99 sq ft. Counter heights should be about 33 to 34 in. To accommodate four students at work, space between counters should be 6 to 8 ft. Just outside each kitchen should be space for a kitchen table and four chairs for serving and eating.

Allowance should be made for adequate ventilation to carry away food odors. Exhaust fan for entire room is suggested. Two duplex electric outlets should be provided in each cooking area. In laundry area, provision should be made for 110/220-V outlet for clothes dryer.

Clothing Laboratory

The clothing laboratory should be equivalent in size to a large classroom. It should include a sewing area (preferably along window wall); grooming area; dressing room area (about 8 feet square), walled off by cabinets on at least one side; storage areas (preferably along walls); and fitting area. Folding doors or screens could be used to separate areas.

Storage should be provided for portable machines, notions, tote boxes (5 in. deep by 14 in. wide by 19 in. long), roll of 36-in. wrapping paper, small articles, textbooks, large fashion magazines, patterns, and teacher's wardrobe, four-drawer, legal-size file with lock. Space is needed for hanging student projects.

Provide adequately keyed electric outlets for machines—suggest one double outlet for each machine—electric outlets for irons and visual-aid machines, one fluorescent light over grooming unit, and adequate light at working surfaces.

Family Living Laboratory

The family living laboratory is used for advanced courses in homemaking: table service, housekeeping, home decoration, selection and arrangement of furniture, entertainment, bed making, home care of sick, leisure time activities, family living, money management, child care, and consumer education.

This is the central core of homemaking facilities. Furniture and equipment should represent advanced solutions of home problems. Space should provide for dining room, living room, and flexible area for home nursing, child care, home furnishing, family living, group discussion, and film viewing. There should be at least one plastered wall for experimentation with wallpapers. Hardwood floors are preferred. Folding doors or screens could be used to separate areas.

Furniture and equipment include upholstered sofa and chairs; side tables and coffee table; lamps and vases; sideboard or hutch; drapes (to be made by class); dining room table and chairs to seat eight; card table and chairs; framed pictures (art project); roll-away bed; built-in storage cabinets for magazines and linens; cleaning supplies; vacuum cleaner; electric drill and attachments for waxing and buffing; samples of home furnishing materials; dishes; silver; table linen; curtain and drapery fixtures; full-length mirrors; home nursing equipment; child-care supplies. Supplies should be stored near area where they will be used.

There should be artificial lighting and switches adapted to house situations; com-

Fig. 122

bination outlet for electric iron, pilot light, switch and outlet; electric clock; special lighting on machines; electric duplex outlet spaced at least every 12 ft of available wall space; sink with hot and cold water.

In laying out the prototype kitchen units it should be remembered that there are both instructors and students using them; hence dimensions between counters should be more ample. Figure 121 indicates some minimum dimensions, while Fig. 122 shows a grouping of U kitchens. Fig. 123 shows perimeter kitchens, allowing for a sit-down class grouping at the tables in the center in a rather typical combined food-and-clothing arrangement.

Typically, various kitchen-plan types as well as various appliance types are incorporated into a layout to allow the student to experience their differences. Counter and cabinet types and finishes, even flooring, might likewise be varied while realizing some discretion toward enough common denominators to give order to the total space.

Like planning any laboratory, equipment functions, clearances, and their electrical and mechanical service requirements should be carefully understood, and most of the needs are larger extensions of home situations, such as extra lengths of counter and space between appliances. Unit kitchen plans should also be designed to allow for periodic appliance replacement with new models, sometimes provided for specific consignment by local utility companies, such as accommodating ranges at counter ends to allow for size changes.

A few miscellaneous planning aids should be provided:

- A minimum of 2 linear feet of counter space per student (wall cabinet storage is underutilized in the prototype kitchen and can be more minimal)
- Tackboard or wall behind sink
- A well-located teacher demonstration kitchen counter (an overhead mirror helps too)
- Pull-out bread boards (they save on counter top wear)
- Spread-out storage for student projects, like sewing
- Portable ironing boards (these are better than built-ins)
- Sewing table unit (for use by four works well)

Fig. 123

- Corridor exhibit area for display

Summing up, the home arts area is a place for learning about living; make it as easy and pleasant as life can be for the students starting out.

FOOD SERVICE

Lunchtime can and should be break-time, a change of pace in a place different in feeling and fact from the rest of the day. In reality, it is hard to be efficient in the use of space in schools. Most often lunchrooms must serve other purposes. Time for eating is cut too finely between academic periods. Great numbers must be served in a hurry.

All the more reason and need then to try harder while planning to carefully consider the processes of food preparation and serving, together with seating areas and traffic flow, to give the best chance for table manners to survive and a happy shipshape atmosphere to exist amid the hubbub.

There are enough ordinary problems to be solved in planning a dining and kitchen area to allow consideration of a unique design approach. Like anything that is architecture, it grows from those human needs it is serving, asking: Whom are we going to serve? What are we going to serve them? How will we go about it?

ELEMENTARY AND SECONDARY SCHOOLS

Home Arts; Food Service

Fig. 124

Fig. 125

Fig. 126 Home arts, Linton High School, Schenectady, N.Y.

Fig. 127

The program is made up of three factors: patrons, menus, and operation. Particularly in this part of the school, the allocation and arrangement of spaces and the choice of fixtures must develop for specific reasons in order that the total design be functional.

Systems for a School Lunch Program

Each system is a kitchen and an arrangement for the distribution of food.

1. Conventional kitchen and adjacent cafeteria.
2. Kitchen, central to site, with adjacent and remote serving stations.
3. Kitchen, central to community, with all serving stations remote. "Satellite" is another term for remote.

The Conventional Kitchen A conventional kitchen and adjacent cafeteria are illustrated in Fig. 129. This particular kitchen produces an a la carte

ELEMENTARY AND SECONDARY SCHOOLS

Food Service

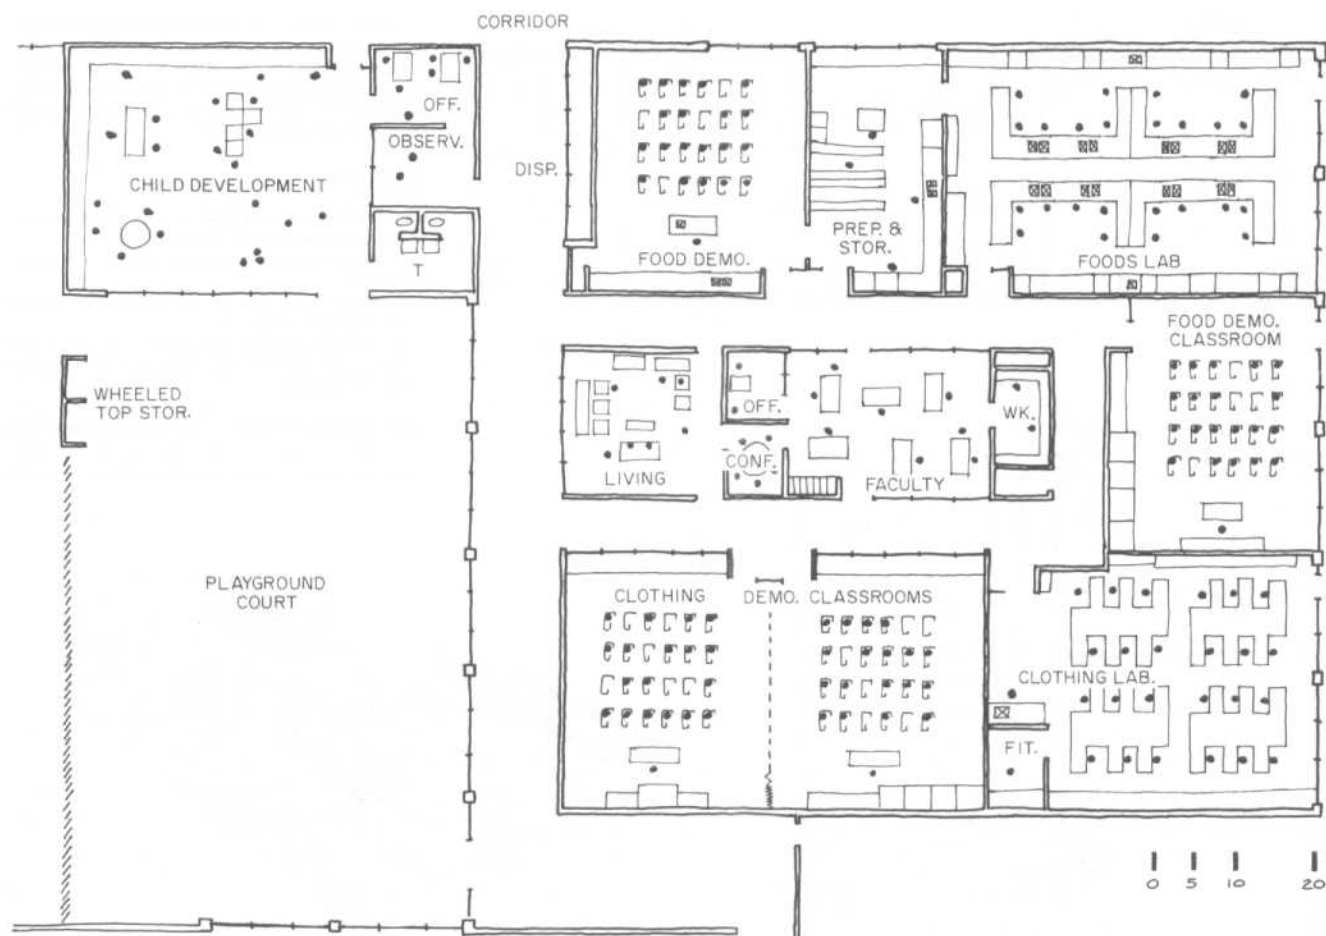

Fig. 128

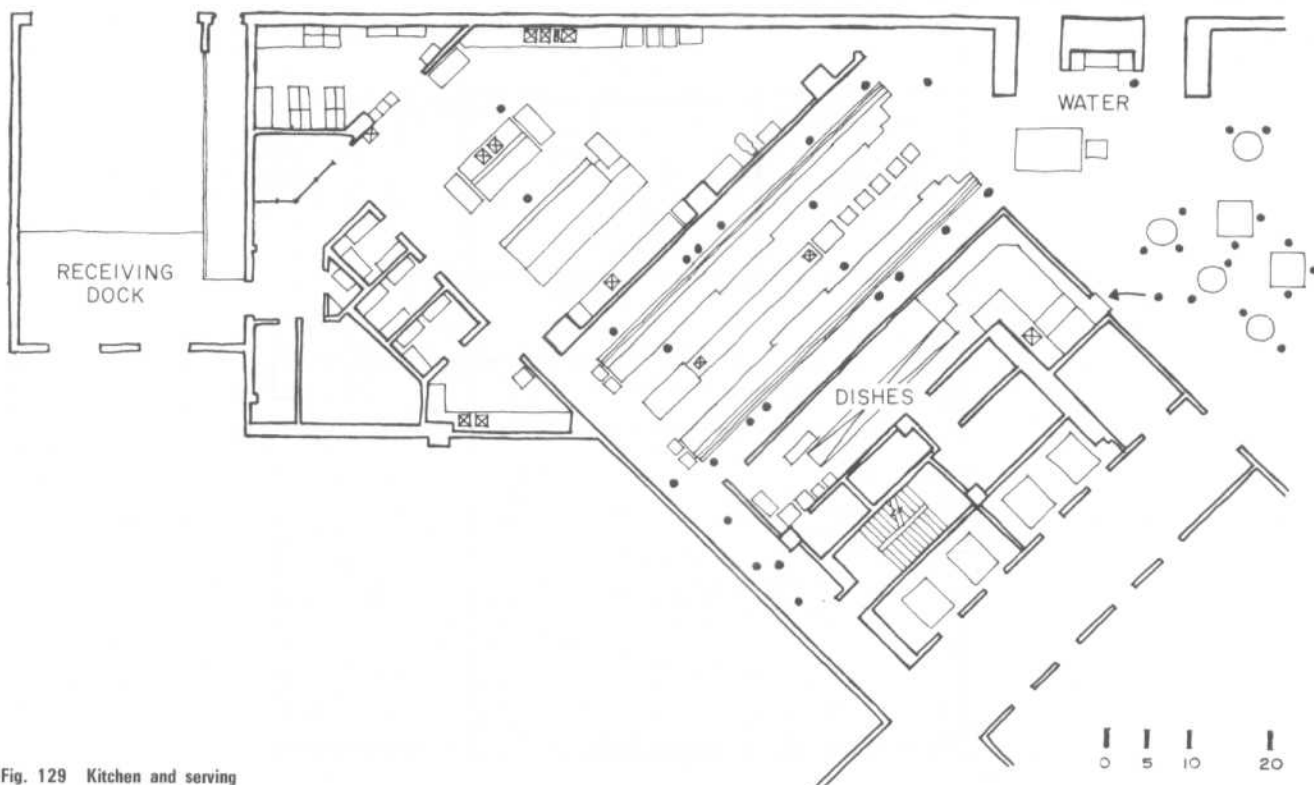

Fig. 129 Kitchen and serving

ELEMENTARY AND SECONDARY SCHOOLS

Food Service

Fig. 130 Kitchen, serving, and dishwashing.

luncheon for approximately 1,100 patrons. Raw foods enter the building at the rear, diagonally opposite the dining room. Food processing follows a straight flow line from receiving to storage to preparation to the counters.

The serving counter adjacent to a conventional kitchen requires little or no cartage of bulk food. In Fig. 130 the distance between prepared food and pickup of trays is but the thickness of a wall. Kitchen personnel assemble trays at both sides of this assembly line. There are no conveyor belts. Trays are set up in advance with napkin-wrapped silver. Output of the line is two trays at a time. Snack bars when they do exist in schools, usually augment cafeteria counter service of a full, hot lunch. Most snack bars serve milk, prepackaged ice cream,

apples, and cookies, as does the small unit in Fig. 131. Some serve soft drinks. The second or third counter in some high schools is an "a la carte" service of prepared sandwiches, packaged snacks, and bakery and soda fountain items (see Fig. 132).

Clean dishes are needed at the serving station; the serving station is adjacent to the cafeteria. Soiled trays and dishes from the cafeteria are usually deposited by student customers at the dishroom. This cycle establishes the location of dishwashing as "adjacent to cafeteria and adjacent to serving," as shown in Figs. 118 and 119.

Large cafeterias utilize conveyor belts because these permit multiple and simultaneous deposit of trays. Figure 133 shows a belt bringing soiled trays from the student and faculty dining rooms to join trays from a third dining room for scraping near the feed end of the dishwasher. The baffle wall between the conveyor and dishroom in Fig. 134 screens that room's activities and sounds from the dining area. Ample dish- and tray-scraping table, disposer, and shelf space can be provided whether or not a conveyor is used.

Flight-type dishwashing machines are commonly employed for patronage numbers as small as 1,000, although conveyor models function efficiently for programs of more than 1,000 people. This choice depends upon many factors, such as the amount of ware to be stored

Fig. 131 Snack bar, serving, and dishwashing.

Fig. 132 Cold food kitchen and a la carte counter.

Fig. 134 Serving and seating arrangements.

Fig. 133 Kitchen between two cafeterias.

Fig. 135 Remote serving station.

ELEMENTARY AND SECONDARY SCHOOLS

Food Service

and handled in racks, the shape of the room available, and the ratio of trays to dishes, etc.

The dishroom is difficult to ventilate effectively. Provide a steam removal exhaust for dishwasher, ample fresh air supply and exhaust, and keep ceiling high for maximum cubic feet of air in circulation.

Kitchen Central to Site Small bulk-food carts can traverse the corridors or elevators from the kitchen to the remote serving station within a building. The hot food, cold food, and pastry carts shown at the serving station in Fig. 134 have been fitted with tongues and hitches. They are pulled by electric tractor from the existing kitchen in the old school building through the new corridors to this location.

Some remote serving stations have dishwashing facilities. The source of clean dishes must be close to the serving station in any plan. Figure 135 shows a small serving station which includes a counter garaging bulk foods under its top, a back bar with refrigerator and small electric appliances, plus a complete assembly of soiled and clean dish tables with smallest floor-supported dishwasher, a window sill for soiled tray deposit, a disposer, and a silver-soak sink.

Any remote station also requires some dish-scraping facility; it is not practical to transport garbage. Note the location of soiled tray deposit in the remote serving station of Fig.

136. The plan permits the flow of high school student patrons to circulate around this serving station segment of the building without any turning back or crossing of traffic. Pick-up food and entrance to the dining area are at the left of the plan; exit and tray deposit are at the right. Within the segment, dishes are processed in a direction toward the serving station.

Kitchens Central to Community The conventional kitchen differs from the central kitchen in that it does not have to accommodate, wash, garage, and load bulk-food carts. Kitchens central to the community differ from the kitchen central to a building because community bulk-food carts and kitchen cart spaces are large, and these carts are invariably transported by motor vehicle. Each of those shown in Fig. 137 is strapped into place along with a cart of trays inside a truck. The truck is fitted with a hydraulic tailgate to adjust to the various unloading conditions at community schools. Thus, an adjacent, well-appointed loading-dock facility is imperative. If located in a cold climate, the loading dock can be enclosed.

Compartmented trays used in lieu of dishes travel in carts to the remote serving station in the community and are returned to the central kitchen for dishwashing, as shown in Fig. 137. This largest of carts keeping bulk, hot, and cold food has a serving top. It therefore has many applications as a portable counter, for example

for service in the classroom to kindergarten tots and first graders. Figure 136 shows it substituting for a section of built-in counter.

Anatomy of a Kitchen

An efficient kitchen has a straight-through flow of foods being processed from the raw state to finished and ready to serve.

<i>Its Departments</i>	<i>Their relationship</i>
Receiving and trash rooms	Near dock
Dry storage	Near the receiving and adjacent to the kitchen
Refrigerated storage	Near the receiving area and adjacent to the kitchen
Pre-preparation sinks, tables	Between refrigerated storage and vegetable prep
Vegetable preparation	Adjacent to the cooking battery
Cooking	Adjacent to the cooking battery
Baking	Can be remote, adjacent to the kitchen
Pot washing	Must be near the cooking area, the baking area or both
Salad making	Near refrigerated storage, can be remote, adjacent to the kitchen

Fig. 136 Remote serving station.

TABLE 7 Kitchen Spaces in Square Feet
(Lunch programs—meals per day)

Department	500	1,000	2,000	3,000
Receiving	50-70	80-100	160-200	240-300
Dry storage*	150-250	300-500	600-1,000	900-1,500

Fig. 138 Serving.

ELEMENTARY AND SECONDARY SCHOOLS

Serving Counters

When the menu is simple and everyone receives the same lunch, tray assembly can be employed for fast service. When food choices are offered, the serving counter is needed to stock and display items. The number of seats in the cafeteria determines the total length of serving counter required (refer to the Food Service Space Requirement Chart). Bottlenecks in student traffic can occur if counters are not of sufficient size, if there are too few cashiers, or if there are not ample seats. As Table 8 illustrates, a counter (35 ft) is required for every 150 to 200 seats. One to two cashiers per counter is recommended. The quantity of seats required is halfway between one-third and one-half of total patrons daily. This formula provides for the peak load in the cafeteria, which will occur during three seating periods.

It is increasingly necessary, with the advent of modular scheduling of classes, to provide for fast pickup of food. For this reason, "scramble" and other configurations should be contemplated as soon as more than one counter is required. This need not increase the quantity of counters. Sections of counters for categories of foods, such as "beverages" or "cold foods"

are arranged separately for direct and quick access.

If the scramble system incorporates parallel units, minimum distance between tray slides is 12 to 13 ft. Duplication of counter sections keeps traffic crisscross at a minimum. The scramble system is most successful in schools or any situations where people eat regularly. The patron who enters the serving area knows

where he is going. The scramble layout in Fig. 138 incorporates a beverage island at the center. Two sides of the island are identical.

The "marketplace" unconnected "sawtooth" arrangement of the counters in Fig. 139 allows the patron to skip certain sections. This layout lends itself to a serving area which is long and narrow. A wide aisle suffices; patron traffic moves quickly.

Fig. 139 Serving and seating arrangement.

TABLE 8 Food Service Space Requirement Chart for School, College, and Commercial Lunch Programs

Planned enrollment or patrons	Seats required	Area designation, sq ft		Number of counters†
		Kitchen*	Serving	
400	170	1,500	700	1
500	210	1,650	800	
600	250	1,800	1,540	2
700	290	1,950	1,540	
800	335	2,100	1,920

2,100	875	4,050	3,850	
2,200	920	4,200	4,230	
2,300	960	4,350	4,230	
2,400	1,000	4,500	4,620	6
2,500	1,040	4,650	4,620	
2,600	1,085	4,800	5,000	
2,700	1,125	4,950	5,000	
2,800	1,170	5,100	5,000	
2,900	1,210	5,250	5,390	7
3,000	1,250	5,400	5,390	
3,100	1,290	5,550	5,770	
3,200	1,335	5,700	5,770	
3,300	1,375	5,850	5,770	
3,400	1,420	6,000	6,160	8
3,500	1,460	6,150	6,160	
3,600	1,500	6,300	6,540	

* Kitchen space:

150-650 students = 3 and 4 sq ft per student

650-2,000 students = 2 and 2½ sq ft per student

2,000-6,000 students = 1½ and 1¾ sq ft per student

† Counter = 35 to 40 linear feet of serving equipment.

Dining Rooms, Seating and Plan Arrangements

School dining rooms most often double as study halls and lecture rooms; they are multi-purpose and must include functional aspects which are incompatible with a dining atmosphere (see Fig. 140).

While bywords like washable, easily maintained, movable, durable, and economical do and must prevail in selecting furnishings and finishes, the call for character and creativity must then come on stronger. Color, plan arrangement, and the whole "feel" of the room must have a sense of order and sureness, some predominant theme.

Commonsense planning can eliminate a lot of irritations. A partition between the dining and serving area can screen off the clutter, noise, and distractions of the serving lines. The utility aspects of cashier stands, silver and condiment stands, and water stations can be less obtrusively located and "camouflaged" in the room decor. Look at the more attractive commercial cafeterias, their subduing of the "working parts," and the pleasant, sometimes striking, overall look designed with similar criteria. They avoid "namby pamby" colors, too many materials, and disorder; instead, they have an organized theme of color, form, and materials, and acoustical materials too, for noise is a prime chaos contributor.

"Mess-hall"-size spaces, undivided, are unnecessary, as a screen or partition can cut down simply on the vastness and accumulation of noise and visual business. Carpeting with color, texture, and a whole environmental control and order of its own and which is virtually stainproof can be used now to further minimize noise. Or, if the room has to serve for gym or coke dances, all kinds and colors of resilient flooring materials are available.

While air conditioning and new efficient lighting have made windows functionally unnecessary, still a "room with a view" is worth looking into, or out of, and an outward visual release can generate calm with the apparent increase of sensed space. An outlook view would be all the more appropriate if the school's instructional areas are primarily windowless. Good ventilation is another criti-

ELEMENTARY AND SECONDARY SCHOOLS

Food Service; Physical Education: Gymnasiums

Fig. 140 Seating arrangement.

cal item. Food odors are best controlled by bringing air into the dining room and exhausting it through the kitchen at 30 air changes per hour minimum. In the kitchen itself, 30 to 60 air changes are desirable.

Space and how it's used, though, is the key. A good guide is to allow 12 to 15 sq ft per seat in planning the dining space. Smaller tables will use more space, but will encourage more quiet conversation. The small table for four persons, which makes most of floor space and yields the most elbow space when standard trays are placed on its top is 30 × 48 in. Four standard 14 × 18 in. trays will not fit on a 36 in. sq table. Mixing round tables with rectangular ones relieves the monotony of the repetitious, institutional look. Manufacturers provide tables which are 29 in. and 24 in. high for the younger children. All kinds of table and seating types—folding, jackknifing, folding into walls, stacking—allow for countless arrangements and flexibility.

To review briefly, in planning for food service, the simple objectives are getting the food to the student, getting the students to the food, and providing an enjoyable dining atmosphere.

PHYSICAL EDUCATION

Gymnasiums

In this keep-fit, diet-craze, body-bent, sports-minded age, physical education programs have gained a new focus, and top-notch facilities are getting built, from multipurpose 40 × 60 ft rooms in the elementary grades to multi-gyms and specialty spaces in the large high schools. The basketball court is the common denominator of the gymnasium plan, overlapped by other court layouts and enlarged for other uses including spectator seating.

Making up the right kind of environment are the factors diagrammed below. Places to play well in should be well designed in all ways, more than super-space boxes. The gymnasium, the whole physical education unit, is most always a place for other performance use, and so its internal planning relationships must serve its everyday use, but its public use sets other demands for its relation in the total plan. Its great volume begs other considerations for separate, special ventilating systems, structural systems, and related massing concerns of its exterior (see Fig. 141).

Fig. 141

The gymnasium complex in Fig. 142 shows several relative points: direct relation to parking and playfields, public lobby space and rest rooms, double-decking of locker facilities and auxiliary, or balcony, gym space equating to the height of the main gym, "boys" and "girls" gyms divided by a folding partition

opening to allow the total space for exhibition game use, with bleachers folding out and down from the balcony gyms, and the whole volume given better scale and character inside and out with beams and undulating angular roof/ceiling treatment.

Table 9 gives recommended dimensions for various gymnasium sizes.

The basic relationship of elements and planning fundamentals for a gymnasium are shown in Figs. 143 to 147. In the typical school the staff for boys and girls have a working relationship to each other and a responsibility for instructional supervision to both the gymnasium and locker spaces, as well as a preferred, as-direct-as-possible relationship to the total school, or corridor entry. The staff offices are, in effect, control centers. The locker rooms should be so located and planned to allow direct access to the outdoor playfields as well as to the gym.

Expansion potential should always be considered, and the physical education parts should not be "locked" into other plan elements. As enrollment increases, oft-times added practice gyms or auxiliary spaces like wrestling rooms, a pool, or more locker space may be needed.

The gymnasium itself develops from many functional and prescribed requirements as are noted on Fig. 143.

Figure 148 illustrates a field house complex, with large balcony gyms (above the locker areas) flanking the main exhibition gym. Spectator seating is accommodated by folding/rolling bleachers at both levels. Those at the main floor level can be folded back against the locker room wall to allow more usable space in the main gym and those on the balcony can be rolled and folded back, or could be detailed to fold up to form a wall between the balcony and main gym spaces.

TABLE 9 Recommended Dimensions in feet for Gymnasiums

School	W	L	W ₁ *	L ₁ *	Seats
Small elementary	36	52			
Large elementary	52	72

Fig. 148 Field house development, senior high school Englewood, Colo. (Perkins & Will—Wheeler & Lewis, April 15, 1957.)

Figure 149 illustrates a 2,400-student high school physical education complex where the main activity areas develop above a base floor of lockers and auxiliary space. The result is architecturally well articulated, saves on ground coverage for more playfield space on a restricted site, allows for separate student and public access to the pool, provides on-grade access to the playfields, and clearly divides the gyms into usable components (see Fig. 150).

Locker Rooms

Locker rooms need not be the noisy, steamy, smelly, dimly lit spaces too many have been. Because they are very concentrated areas of complex plumbing and ventilation and hard wear requirements, they can be expensive to build and are too often made too minimal to properly function and be maintained.

Locker rooms are busy places for students in a hurry, dressing in never-enough room, with showering humidity, outdoor muck, and emotional pitch and pique as added realities. A very functional plan is a must, one that thoroughly considers traffic flow, the realities of body dressing clearances, locker door swings, clothing storage, systems for towel distribution, uniform drying, and supervision and discipline. Equal concern must be given to good and durable lighting, plumbing, ventilation, and finishes (see Fig. 151).

ELEMENTARY AND SECONDARY SCHOOLS

Physical Education: Gymnasiums, Locker Rooms

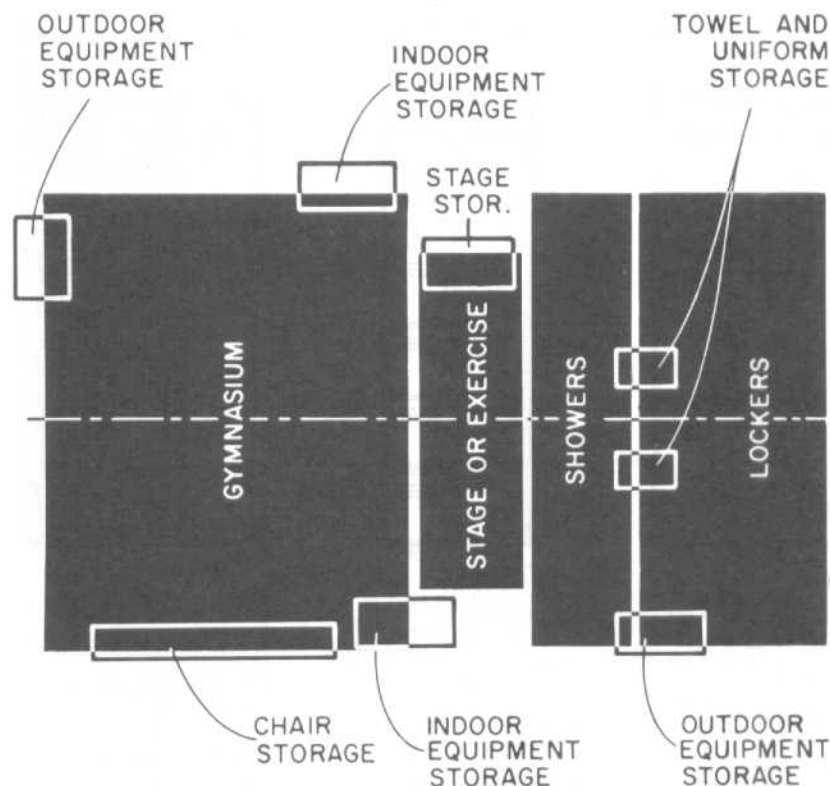

Fig. 150

Unless the increasingly seldom used system of central basket storage is utilized for clothing storage, the number and ratio of gymsuit to street clothes lockers are determined by the formula

$$T \times N/P = S$$

where T = number of students to be enrolled
 N = number of times/week student in course

P = number of periods/week that physical education is given (hours/day \times days/week)

S = number of street clothes (dressing) lockers required

T also then represents the gymsuit lockers needed, and $T/S = R$, or the ratio of gymsuit versus street clothes lockers, varying as shown in Figs. 151 and 152 and determining the total space required for lockers.

The standard type of full-length locker should be set on a masonry base to facilitate cleaning. The unit should be complete with two top shelves, ventilating grilles, and four hooks for hanging clothes. Some type of locking device should be furnished.

Wire baskets may be used in place of the small lockers for the storage of gym clothes. Although in some cases the baskets have been mounted in a fixed position, it is more desirable to place them on trucks which can be locked in a well-ventilated storage space. The basket system is generally more difficult to manage than the locker system.

A common arrangement is to provide one large dressing locker, together with six storage lockers. This permits the student to have a large locker in which to hang his street clothes and also provides him with a small locker for the storage of gym clothes.

Figures 153 through 157 show various shower arrangements and dimensions for group showering. Additionally, it is still common practice to provide some private showers for special demand usage. As the illustrations indicate, there is a trend to prefabricated plumbing arrangements wherein the plumbing is not built into the walls, reducing its installation and repair costs. It is also quite common to equip the facility with preset temperature valves or graduated settings in walk-through showers. Figure 158 shows the height range for shower heads.

The arrangements shown here are for a 500-student junior high school boys' locker room (Fig. 159) with center benches, a 1,500-student high school girls' locker room (Fig. 160), and the boys' and team locker room (Fig. 161) with benches integral with the locker bases. Note the inclusion of two private showers in the girls' locker room, the supervisory location (and windows) of the office in both areas, the walk-through showers in the one, and showers and drying areas in the other.

Figure 162 shows a very compact, well-organized complex of team locker bays, permitting unused bays to be locked with sliding gates while providing good access from the opened bays to the shower facilities. Figures 163 and 164 show various details and arrangements providing for uniform drying and storage.

supporting locker facility. In many states separate locker facilities are required for pool use. Note in the locker room layout, the entry into the pool via the shower room, a basic requirement.

AUDITORIUMS

The school auditorium is frequently used as a center for community affairs. It should be so designed and equipped that it may be used effectively by all groups—amateurs, professionals, youth and adult alike. The use of this facility will extend over a wide range, including concerts, plays, motion pictures, forums, and other forms of presentation.

The stage is the essential educational facility, for it is on the stage that young people have the opportunity to learn to present themselves before large groups. It should be designed for ease of movement of performers and stage sets. Areas that support production, such as stagecraft, band room, choral room, storage, dressing rooms, and restrooms, should be located to give rapid and convenient access to the stage.

Many school officials have expressed a preference for auditoriums without any natural lighting. Absolute light control is essential for a good performance. In some schools, windows can be darkened by automatic controls operated from a central point. Stage lighting should be flexible and simple enough to permit amateurs to operate the equipment effectively.

The seating of the auditorium is not as important from an educational point of view as it may be from the community use standpoint. There is no need for the school auditorium to seat the entire student body. It is best designed when the audience is small enough to make participation possible in group discussions and to ensure a reasonably full assembly area under most types of usage. A capacity of 300 to 800 would normally meet all school requirements. Additional capacity would be dictated largely by community use.

The school auditorium in Figs. 171 and 172 will comfortably seat about 850 students. A ticket booth is located in the foyer of the auditorium lobby. This lobby provides ample circulation space immediately outside the seating area. The placement of seats and aisles gives good traffic circulation. The entire seating area has adequate sight lines giving good view of

ELEMENTARY AND SECONDARY SCHOOLS

Auditoriums

the stage from all seats. The front of the stage platform extends beyond the main curtain, providing area for a speaker or discussion panel while the main stage is being set up for a following performance. The stage curtains, teasers, borders, and cyclorama shown on the drawing are adequate to support the various stage activities. The ample corridor space and doors back stage provide rapid circulation of performers, stage crews, and properties. The band and choral rooms are conveniently located with direct access to the stage. Music practice rooms are also used as dressing rooms for performers. This auditorium

has direct access to a delivery area, which is convenient when delivering or removing stage properties.

This auditorium unit (Fig. 173) is a community art center. Integration of all the arts with the auditorium is highly desirable.

The educational program of the school and the needs of the community resulted in this extensive auditorium center (Fig. 174). Over 1,400 seats are provided on the main floor and balcony area. Adjacent to the stage is a workshop room where scenery and properties may be designed, built, and moved directly to the stage. This room also provides storage

for flats and props. The area in front of the stage is large enough to seat a band or orchestra with adjacent storage for music chairs and stands. Student and adult performers are provided with dressing rooms, make-up room, and toilets.

Figures 175 and 176 illustrate an auditorium unit where considerable emphasis is placed on teaching and preparation for theater, television, and radio productions. This design may be considered more advantageous for student use than for use by community groups. Note the relation in area of the stage and seating space.

DIAGRAMMATIC SCHEME 1 DIAGRAMMATIC SCHEME 2

Fig. 1

Waiting Area

The waiting area is provided as a reception area, as an informational resource area, and as a place for students and others to wait for their appointment with the counselors. This room should be sufficiently large to provide space for a secretary-receptionist and for one student for each counselor available. In addition, there should be space available for three or four additional persons, such as parents or teachers who might be accompanying the student. Thus, for a school which has three counselors, waiting space should be provided for about seven or eight persons.

In order to provide a smoother flow of traffic, and also to minimize possible embarrassment to those students who appear to have experienced an emotional disturbance during the counseling interview, it is desirable that exits other than through the waiting area be provided for students leaving counseling offices. (See Fig. 1.)

Counselors' Offices

The counselor's office is the setting for the interview. There should be an office for each counselor. The interview usually involves only the counselor and the student. However, at times other persons such as a teacher, the child's parents, or another professional worker, such as the visiting teacher, are called into conference. Since the interview

is regarded as confidential, the room should offer privacy, and should be reasonably soundproof. The use of partial partitions is not satisfactory.

Small Conference Room

The small conference room will be used for case conferences where as many as 10 persons may be present. It also may be used by such professional persons as the visiting teacher, school psychologist, health and medical services personnel, attendance officer, college admissions personnel, and the school psychometrist or diagnostician for individual testing or for small group (less than 10) testing.

Multipurpose Guidance Room

This room will have many uses. These uses will vary from school to school depending upon the guidance services offered and upon the concept of group procedures in guidance which prevails. The room should be about the same size as a regular classroom. When a multipurpose room as a part of the guidance area is not feasible, some schools make use of a conveniently located classroom. Uses may include group procedures, group testing, and inservice training sessions in guidance. Some schools may use it as a center for information services. (See Fig. 2.)

Storage Room

Storage space is desirable in several of the areas. This could be one area or several smaller areas,

depending on the size of the guidance area and the ingenuity of the architect.

SUMMARY OF LOCATION AND SPACE GUIDELINES

Location

The guidance unit should be:

1. Separate from but near the administrative offices for convenient access to personnel records and certain clerical services. (See Fig. 2.)
2. Accessible by a direct entrance from corridor.
3. Located to provide exits from counseling area separate from entrances, if possible.
4. Readily accessible to students and near the main flow of student traffic to facilitate contact, scheduling, and communication.
5. Readily accessible from a main entrance for the benefit of parents and representatives of community agencies.
6. Reasonably near to related personnel services, such as pupil accounting, health, and psychological services.
7. Reasonably near to the library for convenience in use of display and reference materials.

Space

The guidance unit should provide:

1. Attractive and comfortable reception area with appropriate materials to encourage profitable use of waiting time.
2. Private counseling rooms or offices.

GUIDANCE SERVICES

Fig. 2 Location of guidance unit. (Reproduced from "Administrative Facilities in School Buildings," Special Publication No. 6, U.S. Department of Health, Education and Welfare, Office of Education, Washington, 1957.)

3. Conference room for such uses as case conferences; individual testing; special staff personnel such as the school nurse, visiting teacher, speech correctionist; interviewing by prospective employers and representatives of institutions of higher learning.

4. Multipurpose room adjacent to counseling offices for group testing, group procedures, and inservice training activities.

CLASSROOMS

Major factors to be considered in designing a classroom are the following:

1. Seating and writing surfaces
2. Space and furnishings for the lecturer
3. The use of wall space, including chalkboards, screens, size and location of windows, etc.
4. Facilities for projection and television
5. Coat racks, storage, and other conveniences
6. Acoustics and lighting
7. Heating and air conditioning
8. Aesthetic considerations

Classroom Seating The seating arrangement is the most important feature in determining the size and shape of a classroom. Seating arrangements in a mathematics classroom should provide all students with a good view of the front chalkboard, ready access both to the seats and to chalkboards on other walls, an adequate, well-illuminated writing surface at each seat, a place to set books and papers, reasonable comfort, and privacy in taking examinations. In a class of 50 or fewer students, where a long front chalkboard is desirable, it seems better to have the front wall longer than the side walls. This presupposes that there are more students in a row of seats than there are rows; for example, visibility is better in a classroom having five rows of seven seats than in one having seven rows of five seats. In a room measuring $26' \times 30'$ (Fig. 1), with separate tablet armchairs for 35 students, the seven seats in a row might have a spacing of $3'6"$ between seat centers laterally and $4'6"$ between the end seat centers and side walls ($6 \times 3'6" + 9' = 30'$). Spacing from front to back in a column might be 3 feet between seat centers with 4 feet behind the back-seat center and 10 feet between the front-seat center and the front chalkboard ($4 \times 3' + 14' = 26'$). This pattern allows for aisles of about 20 inches between columns, a width just under the 22-inch "unit width" used as a standard in estimating the number of persons who can walk abreast in a corridor or stairhall. This arrangement requires about 22 square feet of space per student. Lecture halls whose seats have folding tablet arms may allow 15 square feet or less per student.

Close-packed seating arrangements are not the most desirable, but sometimes are necessary because larger rooms are not available. Laws in some states provide that no person shall have to pass more than six others to reach an aisle; hence 14 persons in a row between aisles is an absolute maximum. If 10 to 14 students sit next to each other in a row behind a long strip table or writing ledge, the ledge should be at least 12 inches wide and should provide at least 2 feet of length per person. An arrangement whereby the nearer half of the writing surface in front of each person can fold up and away from the writer gives more room for students to pass. A spacing between rows of 42 inches be-

tween seat centers is adequate for most seating arrangements that use strip tables for writing.

Tablet armchairs are commonly used for seating in college classrooms in the United States and permit rows to be spaced every 3 feet. They are satisfactory for most classes that do not make use of special equipment (such as desk calculators or slide rules), provided they have a large writing surface and a shelf underneath for books and papers. Tablet armchairs may be found either fixed to the floor, fastened together in sets of two to six that can be moved as a group, or individually movable. When chairs are fixed to the floor the arrangement should be one that permits good visibility and ready access. Good visibility may be achieved in three ways: by sloping the floor, by staggering seats in consecutive rows, or by wide spacing.

An arrangement permitting a class of 30 to spread out for examination purposes in a $26' \times 26'$ classroom seating 40 students would be the following (Fig. 2): in each of five rows, spaced 3 feet apart from front to back between seat

centers, let two triples of seats be placed with seat centers 2 feet apart laterally and with a 4-foot central aisle from front to back between triples. In 5-foot aisles at the sides, let movable tablet armchairs be placed next to the fixed seats for lectures and recitations (keeping the 3-foot aisle by the walls), but let these chairs be moved over next to the walls during examinations. If the center chair in each fixed triple were left vacant, there would still be 30 widely spaced chairs available for an examination. Another pattern involves joint activity by two instructors whose adjoining classrooms are separated by a folding partition, and can be combined into a larger room for 60 for appropriate portions of the instruction (Fig. 3).

A Front Platform In front of the students' seating area, there should be enough space for the lecturer to walk back and forth before a long chalkboard. In rooms with more than five rows of seats there is an advantage in having a platform, possibly 8 inches above the floor and extending the

Fig. 1 Seating arrangement in a classroom for 35 students.

Fig. 2 Classroom for 40, with 10 side seats movable.

COLLEGE AND UNIVERSITY FACILITIES

Lecture Rooms

full width of the room, on which the teacher may walk the length of the board without danger of falling off the end. The chalkboard should then be raised correspondingly higher above the classroom floor for better visibility. The mathematics teacher needs a table on which he [she] can place his [her] lecture notes and papers, but it is better to have this table either movable on casters or fixed at the side of the platform where it does not block the view of the chalkboard from the first two rows of students. If an overhead projector is to be used, there must either be a place where it can be mounted permanently at the front of the room, or there must be provision for rolling it in on a cart and connecting it electrically. In the latter case, the front platform might be slightly lower and be accessible by a ramp. The mathematics teacher seldom sits during a lecture but may wish to sit down during an examination. There should be a chair by his [her] table or desk.

A lecture room should be so placed in a building that it is accessible to students without overcrowding of corridors or stairways. Coat racks, adequate bulletin boards lining the corridors, and ample toilet facilities should be provided nearby. The room itself should be arranged so that the audience can see well, hear well, and be comfortable. In part this depends on temperature, humidity, background of light and sound, and seating space.

Projection Systems The large lecture room should be built to accommodate a variety of projection systems that may be used immediately or in the more distant future. An overhead projector requires an electrical outlet near the lecturer's table, placed so that the lecturer will not trip over the cord, and also a screen properly mounted to assure that the entire class has good visibility with minimum distortion. More screens or a wide screen may be needed to enable the lecturer to use two or more overhead projectors at once. If movies, films, or slides are projected from the rear of the room and reflected from a front screen, the room should have a projection booth, or at least a suitable stand and electrical outlet for the projector. Remote controls for operating the projector are desirable. Shades may be required for darkening a room with windows. If the "rear screen" method of projection is to be used, in which the image is thrown onto a translucent screen mounted in the front wall from a projector in an adjacent room beyond the front wall, the building plans must include adequate provision for this projection room.

A room or space for the preparation of transparencies or other visuals is a corollary of their use. Material can be prepared on ordinary paper and copied quickly onto a transparency by a thermal duplicator or similar equipment. Such copies can be posted after the lecture for inspection by students. Storage for such materials must also be provided, as well as for any materials distributed to students to supplement their lecture notes.

Provision for receiving and transmitting television is also an important consideration in planning a lecture room for large group instruction.

Seating and Visibility Good visibility depends not only on the arrangement of chalkboards and of projection screens and equipment, but also to a large degree upon seating arrangements. Factors to be considered are avoidance of ob-

Fig. 3 A classroom divisible into two seminar rooms.

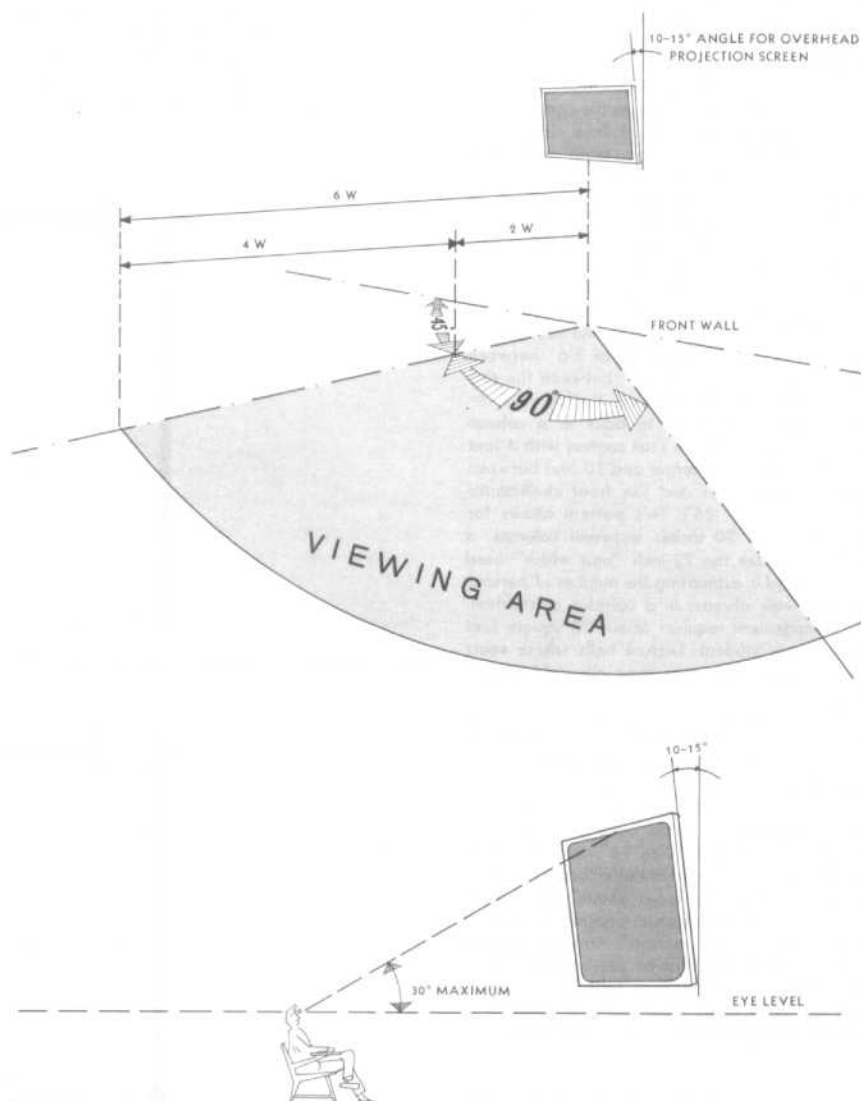

Fig. 4 Optimum viewing angles.

COLLEGE AND UNIVERSITY FACILITIES

Lecture Rooms

structions, slope of the floor and height of the speaker's platform, viewing distance, and the extreme vertical and horizontal viewing angles. It is clear that a good lecture room will not have columns or supports so placed as to block the front screen and chalkboard from any seat in the room. However, when a large demonstration table stands on a platform between the chalkboard and the audience, the lower 12 to 18 inches of the board often cannot be seen by people in the first few rows. In this case, vertically sliding chalkboards are needed so that the writing may be raised to a level where it can be seen by all. A sloping floor in a lecture room will generally add somewhat to the cost of construction, but in many instances it will be worth the extra cost in providing good visibility for all. The object of a sloping floor is to make it easier for a person

to see over or around the heads of those in front of him and to give the impression of a smaller room. If the seats in successive rows are staggered so that the line of sight from one seat to the lecturer goes directly between the centers of two seats in the next row, the rise required per row may be reduced by half. Closely interdependent are the slope of the floor and the height of the speaker's platform. The use of a raised platform for the teacher has advantages in increased visibility in any room seating more than about 40 persons, provided that the table or other furniture on the platform does not block the chalkboard for those in the front rows. [A possible plan is shown in Fig. 5.]

Studies of distances and angles for satisfactory viewing indicate that seats should be placed at a distance from a screen not less than twice nor

more than six times the width of the screen image to be viewed and that the distance from a person to the chalkboard should not exceed 400 times the size of the smallest letter or digit being written. Thus, if the back row of students is 64 feet away, the lecturer should make his letters and digits at least two inches high. Similar studies indicate that the angle of elevation from the eye to the upper part of an object on the screen or chalkboard should not exceed 30 degrees (see Fig. 4). If lecture rooms are built in a fan shape instead of a rectangular shape, the minimum angle between line of sight and the blackboard should be at least 30 degrees and preferably more than 45 degrees. These limitations of viewing distance and angle impose restrictions on the placement of seats for adequate viewing.

Fig. 5 Three auditoriums with common preparation room.

COLLEGE AND UNIVERSITY FACILITIES

Gymnasiums

GYMNASIUMS

Basic Considerations

The type and size of gymnasium facilities needed for a given college or university will depend upon many factors, one of the most important of which is the anticipated enrollment of the institution. A gymnasium planned to serve 2,000 students will, obviously, be considerably smaller than, and different in design and construction from, a facility planned for a university of 10,000 or more students. In other words, planning must be done with future enrollment in mind, and as part of the master plan for the college or university. If a college or university has a definite enrollment ceiling, the building may be planned for this enrollment. If the enrollment ceiling is indefinite, however, the structure should be planned so that additions to the building are feasible. Most universities or colleges should plan for and build for expansion. Gymnasium space is usually planned to take care of enrollments for at least ten years in advance. Universities of 15,000 or more students may find it desirable to build more than one gymnasium structure, each servicing an area of the campus.

Another factor that will affect the type of building constructed is the philosophy of the administration concerning athletics and physical education. Many questions need to be answered before planning begins. Some of these questions are:

- * Will all students be required to take physical education for one, two, three, or four years?
- * Is the required program in physical education to be broad in scope; i.e., will a great many opportunities to develop sports skills be extended to students?
- * Is teacher education in physical education to be part of the program?
- * What responsibility does the college or university take for the physical education, recreation, and fitness of its faculty?
- * Is it anticipated that research in physical education, health, and recreation may become an important aspect of the program?
- * What is the scope of the varsity athletic program? (The facility requirements are considerably different if varsity teams are to be fielded only in the major sports.)
- * What will be done to provide facilities for an expanded program of intramurals and extramurals?

Principles of Gymnasium and Construction

Indoor facilities for sports and athletics should be planned so that all activity areas will be available to both men and women. It is unwise to identify facilities as men's or women's athletic areas. Good planning will permit easy

access to all areas from both the men's and women's locker rooms. This type of planning permits the flexibility necessary for efficient utilization and control.

The space used for permanent seating of spectators at athletic events should be kept to a minimum unless space and funds present no problem to be considered. Roll-away or folding bleachers should be used in order to utilize efficiently the space available. Most colleges and universities cannot afford to invest large sums of money nor give large areas of space to permanent seating which is used only a few times each year.

The health and safety of those using the building should be a prime consideration in planning of all activity areas. The disabled and the aging should also be considered.

The construction of the types of facilities and the allocation of adequate square footage to handle a broad athletic and intramural program will provide more than enough gross space for a two-year physical education requirement for all students.

The traffic patterns for a building should be carefully studied. Lockers, showers, and towel rooms should be centrally located in the building so that they may serve all activity areas. Easy access should be provided from the locker rooms to the playing fields adjacent to the building.

Storage rooms for equipment and supplies should be carefully planned and functionally located. These rooms should be of three types:

- * Central receiving storage room, to which all equipment and supplies are delivered. The warehouse storage room should be accessible by truck.
- * Utility storage rooms located adjacent to gymnasiums so that bulky equipment may be moved to the floor and back to storage with limited difficulty. Overhead doors or double doors should be large enough to permit free movement of heavy equipment.
- * Supply rooms with an attendant's window opening to the locker rooms.

Off-season storage rooms are critically needed. The type of equipment to be moved and stored will define the dimensions of the room and size of the doors needed. Reserve storage should also be provided.

Location of the Gymnasium

If physical education and athletic facilities are used by all of the students at a college or university, the gymnasium facility should be centrally located in order to be easily reached from both the academic buildings and student housing. Physical education facilities, to serve as teaching stations, must be close enough to academic buildings to make it possible for students to move from the classroom into the gymnasium and back within the time provided between classes.

Buildings used only for intramural and intercollegiate activities may be located farther from classrooms and housing than a general-use gymnasium would be. This is especially true if the activities promoted in these build-

ings are scheduled. If the building is to be used for unscheduled participation of students, however, the amount of use will vary inversely with the distance from housing and other campus buildings.

The Main Gymnasium

The criteria for determining the size of the gymnasium are: (1) the nature of the total physical education program; (2) student load as determined by enrollment and attendance requirements per week; (3) spectator interest; and (4) anticipated enrollment growth.

The physical education building should include one main gymnasium to be used for general physical education classwork, intramurals, and intercollegiate athletic activities in basketball and wrestling. Ideally, the size of the main-gymnasium floor for an enrollment of 4,000 students would be approximately 140 by 140 ft. (Use a rectangular dimension if the facility will be heavily used for spectator sports.) This size would provide for one official and three junior-size (35 by 84 ft) basketball courts, with adequate space between the courts and between the courts and walls. If desirable, folding partitions can be used to provide three practice gymnasiums, each 48 by 140 ft. For the basketball courts, backboards that swing up to the ceiling are needed, since nonfolding backboards would interfere with the court usage for volleyball and badminton. In order to increase the number of other instructional units, electrically controlled wooden partitions or nets (nylon or Fiberglas) should be installed.

If the gymnasium is to be used for intercollegiate athletics, seating must be provided for spectators (3 sq ft per person). Portable folding bleachers which can be easily moved are recommended for seating. Portable knock-down bleachers are not recommended because they interfere with classwork while they are being erected, used, and removed. Cost is also an important factor.

The number of seats to be provided will be determined by the size of the student body, the college community, and the degree to which there is public demand for admittance. The seating capacity should be set at a minimum of one-half to two-thirds of the student-faculty population. In larger institutions, it may be necessary to install roll-away bleacher seats in the balcony, which, when combined with the bleachers on the main floor, will provide the required number of seats.

The varsity basketball court should be laid out lengthwise in the center of the gymnasium. If the dimensions of 114 by 145 ft are provided, 25 ft is left on either side for bleachers. A minimum of 5 ft should be left between the first row of seats and the outside boundary line of the court.

Where a permanent balcony is required, it is necessary to plan the line of vision so that the sidelines of the varsity basketball court are plainly visible to the spectators. In this case, the folding bleachers on the floor should be planned to conform to the same line of vision. With the use of roll-away bleachers, added

Planning Areas and Facilities for Health, Physical Education, and Recreation, rev. 1966, The Athletic Institute, Merchandise Mart, Chicago, Ill.; American Association for Health, Physical Education, and Recreation, Washington, D.C.

COLLEGE AND UNIVERSITY FACILITIES

Gymnasiums

teaching stations can be provided in the balcony area.

If the gymnasium is to be used for intercollegiate sports, the number of entrances and exits equipped with panic hardware should meet fire regulations and be ample in number to control spectator traffic. Spectators should be routed in such a manner that they do not cross the playing courts or other activity areas in the gymnasium.

The height from the floor to the beams in the main gymnasium should be such that in normal use of any of the courts, the balls or badminton birds will not strike the lowest ceiling beam. This height should be a minimum of 22 ft to accommodate the rope climb, basketball, volleyball, and badminton.

Where intercollegiate basketball is played, there should be adequate provision for sports-writers. A press box is recommended if conditions permit. The placing of tables adjacent to playing courts is not a good practice. Provision should be made for telephone and telegraph connections, for reception and transmission lines for television, for timing and scoring devices, and for the operation of a public-address system, including stereophonic music.

When an area is designed for an activity which will require the use of a piano, phonograph, or tape recorder, a space should be provided for storing this equipment. It is preferable to have a space recessed in the side-wall near the place where the instructor will stand to lead the class. Electrical outlets which will provide current at all times will be needed for such equipment as amplifiers. A locking, sliding door should be installed for the protection of the instruments as well as the students. All instructional equipment should be on movable carts.

In addition to the niche described above for the storage of the piano and phonograph, there should be a storage room adjacent to the main gymnasium of sufficient size to accommodate the storage of all types of equipment, such as roll-away standards, mats and gymnastics apparatus, and chairs.

Other audiovisual aids can include still and movie projectors, daylight-projection screens, television sets, a scoreboard, a clock, chalkboards, and an intercommunication system.

Concrete is commonly used as a base in constructing the floor of the main gymnasium. Sleepers of 2 by 2 in. up to 2 by 10 in. are laid on edge. Maple tongue-and-groove is the most popular type of wood finish.

It is suggested that a glazed-tile wainscot be carried up to a height of 7 or 8 ft. From that point to the ceiling, the concrete or cinder block should be painted with a light-colored paint.

Experience has shown that, in general, natural lighting methods have not proved satisfactory. Mercury-vapor or fluorescent lights with diffusion panels have provided satisfactory illumination.

There is some evidence that suspended tracks are no longer favored by physical education directors. However, if there is no balcony in the main gymnasium, a track serves as space for spectator seats and also for additional teaching stations.

If a track is constructed, it should be at least 8 ft wide and 10 ft above the gymnasium floor. The surface should provide good traction, and the curves should be banked.

The Lobby The purpose of the lobby is to furnish an area for the control of admission and distribution of traffic and the provision of information. It should contain well-lighted and

locked display cabinets, bulletin boards, and directories. These units should be recessed and flush-mounted. Public telephones should be located in or adjacent to the lobby. Other service facilities needed, as defined by the program, should be provided. Examples of these needs are ticket booths, planters, and special decorations. The lobby should be attractive and of sufficient size to accommodate traffic needs. Vestibules should be included for climate control.

The general administrative offices of the building should be located near the lobby. Corridors should lead from the lobby to locker rooms and spectator areas. Probably the most serviceable and attractive floor for the lobby is terrazzo or a material of similar quality. The walls should be constructed of durable material.

A large checkroom for outer wraps should be placed adjacent to the direct line of traffic, but in an alcove or a side room in order to prevent congestion. The location and arrangement of the checkroom should serve the daily needs of the building as well as the needs of special occasions. The room should have a long, low counter covered with brass or stainless steel, and it should be possible to lock both the room and counter opening when the facility is not in use. Racks permanently numbered for checking coats and hats should be installed. Shelves should also be provided for storing packages and bags.

Toilet and washroom facilities for men and women should be located near the checkroom. Adequate stairways or ramps should lead from the main lobby to balconies or other spectator areas above the first floor.

Offices The central administrative offices serve as the nerve center of the entire physical education plant. They should be located near the entrance of the building, since all who have business with the department will first come to these offices. The office of the director and those of the various faculty members should be adjacent to a large central office which will serve as the workroom for the secretarial and clerical staff, as a repository for all departmental records, and as a reception center and waiting room for persons who have business with the department.

The work area of this central office should be separated from the reception-waiting room area by a counter. The reception-waiting room should open into the main corridor of the building. A large closet should be provided adjacent to the work area for the storage of office supplies and records. The administrative head should have his office in or near the central administrative suite. His office should be of sufficient size to accommodate such things as an executive desk, a number of chairs, a file cabinet, and a small work table. This will require approximately 200 sq ft. The central administrative office unit should include a conference room. This room should be near the office of the administrative head of the department. It should be furnished with a truncated conference table large enough to seat the entire physical education faculty, if possible, or the administrative staff in a larger university.

A small cloakroom and rest rooms should be located near the conference room. The chairs for the conference room should be upholstered in attractive colors of vinyl materials so they can be kept clean. The conference room should be finished in light, attractive colors. It is desirable to have a small, murphy-type kitchen for refreshments.

Each member of the faculty with major re-

sponsibilities should be provided a private office. Ideally, each of these offices should occupy a minimum of 120 sq ft and be equipped with necessary office furniture. A workroom with space for a secretarial pool should receive serious consideration.

Classrooms The physical education complex should include sufficient classroom space designed primarily for lectures, discussion, and demonstrations. The number, size, and types of rooms will depend upon the anticipated enrollment and curricular offerings. Institutions offering teacher-training programs in health, physical education, recreation, and safety will have need for more specialized rooms than will those concerned primarily with service and basic instruction courses and varsity athletics.

The sizes of classrooms may well vary to accommodate from 10 to 150 persons. The space per student may vary from approximately 20 sq ft per student in smaller rooms to 12 sq ft per student in rooms for 100 or more persons. Standard classrooms normally seat an average of 40 students. The smaller rooms lend themselves more readily to seminars, conferences and informal discussions, while an assembly room big enough to combine large groups for professional lectures, clinics, and demonstrations is essential.

Where class size warrants, a wall clock visible from all seats should be installed. Acoustical treatment, adequate lighting, and thermostatically controlled mechanical ventilation should be considered for all classrooms. Each classroom should be provided with chalkboards, tackboards, and hook strips. Electrical outlets for audiovisual equipment should be strategically located with due regard for the convenient placement of controls.

Windows should be equipped with effective room-darkening devices which are easily operated. A speakers' platform or podium is frequently desirable in rooms designed for larger groups. Large assembly rooms might well be equipped with a projection booth. A rectangular room is more satisfactory for film projection. Transmission and reception of television, including closed-circuit programs, should be considered when planning modern physical education facilities.

In locating room entrances, due regard should be given to traffic control. The rooms themselves should be placed where they are conveniently accessible yet removed from disturbing noise and distraction.

In smaller classrooms, movable tablet or desk armchairs may be used, or conference tables and straight chairs may be preferred. Large lecture halls and assemblies should be equipped with numbered tablet or desk chairs secured to the floor and so arranged as to provide visual efficiency. It is highly desirable that convenient recessed cabinets and closets be provided for storing instructional materials and personal effects.

Auxiliary Gymnasiums

In addition to the large general gymnasium, or gymnasiums, several other gymnasiums may be required for

- Exercise therapy
- Gymnastics
- Weight exercise
- Wrestling and personal defense
- Street-shoe usage
- Dance studio
- General games

COLLEGE AND UNIVERSITY FACILITIES

Gymnasiums

Exercise-Therapy Facilities Two separate areas should be planned for this specialized program: (1) an exercise-therapy room, which can be used as a clinic, designed for individual ameliorative exercises, is the basic requirement; and (2) a gymnasium for adapted activity is necessary for students assigned to this program.

The exercise-therapy room should be on the ground floor if possible, or accessible to an elevator. It should be well lighted, and the walls and floor attractively finished to lend a cheerful atmosphere. The size of the room is determined by the number of students needing this special attention. Approximately 70 sq ft of floor space is required per student. To accommodate equipment, the minimum size of the room should be 1,600 sq ft. Office space should be located within this area, and the office should be equipped with large glass windows for adequate supervision of the room. The room should be well ventilated, with air conditioning provided where necessary. The dressing and toilet facilities should be close to the exercise-therapy room and should be adjusted to the needs of the handicapped. A sink or washbasin should be provided in this facility. Doors and windows to the room should be designed for privacy. A curtained area should be provided for changes of equipment or appliances when privacy is desired.

Permanent equipment installed in the exercise-therapy room should include stall bars, wall weights (pulley), press bar, weight racks, shoulder wheel, finger ladder, hanging bars, overhead ladder, push-up bars, wall charts and anatomical drawings, mirrors (single), mirrors (triple), and walking rails.

Removable equipment should include: plinths (treatment tables) 26 by 72 by 30½ in.; stall-bar benches; incline boards 7 ft by 30 in. by 3 in.; ankle exercisers; a bicycle (stationary); weights (dumbbells); weights (barbells); exercise mats; iron boots (single); iron boots (double); parallel bars (low); orthopedic stairs; rowing-machine stools; scales; an Elgin table (or improvisation of quadriceps exercise table); wrist rollers; neck-traction halters; cushions or pillows; crutches; a wheelchair; dynamometers (hand, spring cable); goniometers; a chalkboard; and a skeleton.

The equipment in an adapted-activities gymnasium should be the same as in a regular gymnasium, with necessary adaptations. This gymnasium should be in close proximity to the exercise-therapy room so that a student can utilize both facilities.

Gymnastic Facilities With the recent nationwide surge of interest in physical fitness, there has been a renewed support of instruction in gymnastics. Gymnastics make a unique contribution toward overcoming a lack of development of the upper body, which is often neglected in other sports. Gymnastics contribute to building strength, agility, flexibility, coordination, balance, and posture. They also contribute to the mental qualities of alertness, daring, and precision; the character trait of self-discipline; and fun and enjoyment. These values, together with those of preventative and corrective action, place gymnastics in a position of major importance in physical education.

In addition to the main gymnasium where gymnastic meets, exhibitions, and other competitions are held before a viewing public, a separate gymnasium should be provided for the permanent installation and storage of apparatus and equipment and for instruction in gymnastics. The dimensions of this gymnasium should be determined by space requirements needed to accommodate the apparatus and

equipment to be installed, by space needs for performance in gymnastics, and by total school enrollment and interest in gymnastics. Ideally, the size of this gymnasium should be 120 by 90 ft, with a minimum ceiling height of 23 ft. This height permits a clearance of 22 ft for the rope climb and is ideal for hanging the various mechanical systems used in gymnastics. Some have found it desirable to install tracks on the ceiling supports to make it possible to use trolleys for moving equipment and for attaching safety belts used in the instruction of trampoline and tumbling.

The safety of performers and instructors should receive major consideration in planning the location and installation of apparatus, equipment, and wall fixtures. Apparatus used in performance should be located so that performers do not interfere with each other when going through their routines. Flying rings should be located so that there is at least 15 ft of free space allowed at each end of the swinging arc. All equipment should be installed according to a plan that will permit, without interference, a full range of movement, including the approach. Mats should be laid completely around the area of performance on horizontal and parallel bars.

Floor plates for attaching equipment should be recessed and flush with the floor. It may be necessary to reinforce the floor to install floor plates adequately where tension is unusually severe. Wall boards should be securely installed to the wall when equipment is attached to it. Apparatus suspended from the ceiling should be securely attached to metal supports.

The ceiling should be acoustically treated. Lights should be shielded and adequate for the program. Doors should be constructed wide enough and without a threshold so as to accommodate the movement of equipment to other areas. Maple has many advantages over other types of flooring. The facility should be air-conditioned in accordance with standard specifications. Wall construction should be of the same materials as recommended for other gymnasiums.

A common failure in planning is to overlook the need for adequate and conveniently placed storage space for gymnastic equipment. If multiple use of this equipment is expected, transportation carts and dollies should be provided. Specifications on size and installation of the various pieces of apparatus and equipment may be obtained from the manufacturers. Ideally, the gymnasium for gymnastics should be equipped with the following types of items: side horses, horizontal bars, long horses, parallel bars, bucks, trampolines, mats, rings, and other special apparatus.

A gymnastic landing pit, 10 ft wide, 20 ft long, and 30 in. deep, filled with sponge rubber—for use with parallel bars, horizontal bars, still rings, and tumbling—is a new development in construction for gymnastics.

Weight-Exercise Room This room should contain a minimum of 2,500 sq ft of floor space. Such space will provide a weight-training area and space for the practice of official events in competitive weight lifting. It is recommended that the floor of this room be covered with a durable, resilient material. A flooring of this type makes it unnecessary to use weight platforms, which are essential to protect a maple or other wood flooring.

The weight-lifting area should be roped off and should be approximately 15 by 15 ft for the practice of official lifts. The rest of the room may be used for exercise with barbells, dumbbells, isometric cables, etc. Several full-length

mirrors should be installed on the walls. Barbell and weight racks should be attached to the walls so that the room may be kept tidy.

Wrestling and Personal-Defense Room This room is designed for wrestling, judo, and personal defense activities. The ceiling should be of acoustical material and should be a minimum height of 12 ft. It should be rectangular in shape and should contain two square 40- by 40-ft mats. The floor area not covered by the regulation mats should be covered wall to wall with the same type of mat material. The room should be at least 40 by 80 ft. A satisfactory standard is 40 sq ft per student during peak usage.

The floor of the wrestling room should be constructed of, or covered with, resilient materials to prolong the life of the mats. These materials may be rubberlock products, other newly developed resilient materials, or wood. Concrete is not recommended. The mats should be of plastic-type materials and the walls should be covered with resilient materials up to 5 ft above the floor on all sides. Adequate lighting which is properly screened and forced ventilation are essential in this room.

Street-Shoe Usage Room This room should be of sufficient size—70 by 90 ft—to care for the groups for which it is needed. A floor for street-shoe usage may be needed in any size college or university, or in a program with a variety of offerings. The floor most commonly used for this purpose is hard maple, tongue-and-groove, conventional gymnasium flooring. Square dance, folk dance, social dance, physical education for elementary teachers, marching and band practice, and similar activities can be conducted on such a floor. The demand of special college and community events which need to be served, such as musical and drama production, fairs, and carnivals, may be met. The "make-up" room or "warming room" for department and college outdoor programs can be housed in this area and can be served through a door leading to a corridor and immediately to the out-of-doors.

This street-shoe room, when not scheduled in some manner as indicated above, can serve the purposes of any regular gymnasium if so planned in its equipment and floor markings. The floor will need some extra maintenance for the hard use it will receive, but the desirability of the activities which may be scheduled on it will justify the usage and resultant wear.

Dance Studios Dance areas should be provided to serve the departmental and student needs and to afford opportunity for individual and departmental development. Some of these areas are specific and may be limited to forms of dance activity. Other dance areas are versatile and may serve several purposes. Large colleges and universities with a variety of courses may need to plan for one or more of each of several dance-activity rooms. Classes should be advantageously scheduled for the purposes of floor maintenance or equipment moving. The types of dance areas suggested are discussed in the material which follows.

Main Dance Studio This studio, which should measure no less than 56 by 56 ft, will provide for a class of up to 36 students in modern dance, ballet, or some other dance form performed in bare feet or with soft-sole dance shoes. The floor, which should be of conventional gymnasium construction—tongue-and-groove, select maple—should be free of floor plates, plugs, and other installations. The ceiling height should be 22 ft to be proportional

COLLEGE AND UNIVERSITY FACILITIES

Gymnasiums

with the room and to give the feeling of height in leaps.

The room should have wall mirrors along one wall—24 ft in length, 6 ft high, and with the bottom being 2 ft from the floor. The mirrors should have a draw drapery controlled by cord pulls. Ballet bars (hand rails) should be installed on two opposite sides of the room at ascending heights of 3, 3½, and 4 ft above the floor.

Audiovisual equipment should include a tackboard, a chalkboard, a hook rail, and a lockable glass-front bulletin board. An amplification system—for a record player and tape recorder—on a roll-away table should be recessed into a lockable cabinet with a sliding door. Other cabinets should provide space for musical instruments, records, music, costumes, and other properties. Some dance studios may have a grand piano in the room. It may be desirable to have an area where a grand piano or an upright piano can be stored when removed from the floor. Storage cabinets for stage equipment, levels, and other items should be provided since floor storage of materials not actively used markedly diminishes the floor space usable for dance activities.

Main-Dance-Studio Balcony Current plans of some major institutions may be considered desirable in the provision for a hanging balcony or a balcony over other class or service areas. This balcony can provide 100 or more seats for viewing activity on the floor of the main dance studio or in the auxiliary dance studio, which can be used as a stage area for the main dance studio. Access to the balcony may be gained from the dance-studio floor through a lockable control door or from the second-floor service hallway. The balcony will provide opportunity for practice-performance viewing from the balcony level by the members of a dance group or will make it possible to seat visitors for an invitation performance.

Auxiliary Dance Studio An auxiliary dance studio of 56 by 40 ft with a ceiling of 22 ft can be located adjacent to the main dance studio on the side opposite from the balcony and can be separated by appropriate folding doors and draperies. This studio can serve as a stage for small concert productions or class projects. Several institutions have successfully constructed such a facility. Traveling draperies suspended from the ceiling can be run on tracks and can be controlled electrically to serve as the traditional "flats" used in staging and in making up a backdrop behind which dancers can cross over. When not used, the draperies can be withdrawn from the staging area and can be stacked along one wall. Stage lighting can be developed to give illumination from the ceiling, from the stage side of the divider, from "projecting" semi-cones in the ceiling of the main dance studio, and from "spots" in the balcony.

This dance studio will need to include those features desirable for the program needs as are included in the main dance studio: ballet bars, mirror, cabinets for classroom materials, and a roll-away table with record player and tape recorder. In addition, there may be a need for piano and equipment storage rooms.

Dance Rehearsal Room One or more dance rehearsal rooms of a minimum of 400 sq ft each will contribute to the development of students in dance who need small-group practices and extra rehearsals. A chalkboard, tackboard, and rolling table for tape recorder player should be provided in such rooms. The table should be

housed in a recessed, lockable cabinet. Other lockable cabinets will provide needed storage space for dance practice materials. Ballet bars and mirrors will add to the usefulness of such a room.

Dance Property Construction and Storage Room Flats, levels, and other properties can be made and stored in a room of approximately 25 by 30 ft. This room should be located adjacent to the main dance studio and should have wide double doors with a removable mullion so sets and properties can be moved in and out. The room should have a high ceiling to allow sets to be constructed and moved to a vertical position or to the finished position for painting. Drawers and cabinets, some lockable, a sink with hot and cold water, lumber racks, work counters and tables, and electrical outlets are essential in the planned structure of the room. Tackboards, bulletin boards, and lockable, glass-front display bulletin boards are desirable.

Dance Costume Construction and Storage Room The size of this room will vary according to the program needs for costume construction and the storage needs for costumes made and retained in the department. The room will probably be best used by having cabinets in close-order banks, somewhat as bookcases are placed in the stacks in a library. This will free one end of the room for clothing construction. Costume-storage cabinets should have racks for hanging and bins and drawers for storage. Units can be planned so as to be comprised of several components, which may be used as desired for separate assignment to clubs, groups, or projects.

Cabinets for material and equipment storage, wall-attached ironing boards, an automatic washer-drier, a three-way mirror unit, a washroom basin, a large cutting table of 4 by 8 ft, and a counter sink are additional necessities.

Game Room This is a multiple-purpose room, and its use will determine its dimensions. It should be large enough to accommodate at least six table-tennis tables. A ceiling height of 12 ft is adequate. The room should be equipped with a public-address system and record player for instructional and recreational activities, including social and square dancing. This room should be accessible from the lobby or from a building corridor. It should have some kitchen facilities and a hard-usage type floor. The disabled should be considered in the planning.

Special Instructional and Activity Areas

Handball Courts Handball is a vigorous competitive sport long recognized as an essential activity for a college physical education program. Depending on the size of the institution and the expressed interest in handball, one or more batteries of four-wall handball courts should be provided. The official size of a handball court is 20 ft wide by 40 ft long by 20 ft high. Specifications for handball courts can be found in the official handball rule book.

When more than a single battery of courts is to be constructed, the batteries should be arranged so the back walls of each battery are separated by a corridor approximately 10 ft wide and 8 ft high. A corridor located immediately above, and at least 12 ft high, may serve an instructor or be used as a spectator gallery. Corridors and galleries should be illuminated with indirect light.

The back wall of a single court need not be higher than 12 ft. Shatterproof glass may be used to enclose the remainder of the back wall. The use of wire mesh for this purpose is of questionable value. Many courts are satisfactorily used with an open upper rear wall.

Handball courts may be constructed of hard plaster, concrete, shatterproof glass, or a non-splintering, durable wood. While plaster is sometimes recommended, it would be wise to consider courts constructed of other materials because of maintenance costs. Glass courts provide maximum spectator participation, but the initial cost may be prohibitive. Hardwood construction is most satisfactory. Courts constructed with a high proportion of glass walls obviously allow for a large number of observers. Open-balcony construction interferes with individual-court air conditioning.

Front walls may be constructed of hard maple laid on diagonal wood sheathing. Stud-ding should be placed close enough to prevent dead spots. A maximum of 16-in. centered studs is recommended. A costly but desirable front-wall construction is to lay maple on edge grain.

Side and back walls may be of nonsplintering, durable wood such as yellow pine or hard maple. Some side and back walls constructed with 1-in. tongue-and-groove marine plywood have been satisfactory and economical. Hardwood floors of standard gymnasium construction are recommended. Plaster ceilings have proved satisfactory. All interior surfaces should be painted with eggshell-white enamel.

Entrance doors should open toward the corridor and be provided with flush-type pulls and hinges. A small shatterproof window installed flush with the interior surface of the door should be located at approximately average-adult-male eye level.

No fixtures, such as heat pipes, ventilating ducts, lights, or any other mechanical equipment, should project into the playing area. Ventilating ducts and lighting fixtures are best located flush with the ceiling surface. Lighting specifications are available for handball courts. Provision for replacement of burnt-out light bulbs from above is a desirable feature.

A single light switch to control all lights in each court should be placed on the corridor side and near the entrance door. Warning lights, located outside each court, should indicate when a court is being used. By use of a sturdy push button, lights can be turned on when an entrance door is closed.

Refrigerated air conditioning, or at least forced ventilation, is essential for individual courts. The ventilation switch can operate in conjunction with the light switch. Climatic conditions may dictate separate switches.

Squash Courts Squash is very popular in some localities and should be provided for in the physical education program. It is recommended that at least one single and one double squash court be included in a physical education complex. A singles court is 18 ft-6 in. wide by 32 ft long by 16 ft high. A doubles court is 25 ft wide by 45 ft long by 20 ft high. The number of courts should be determined by the interest in this activity in a given community.

It is possible to install movable metal "tell-tales" across the front of handball courts so they can be used for squash. Construction features of squash courts are similar to those of four-wall handball courts relative to floors, walls, ceilings, lighting, heating, and ventilation.

COLLEGE AND UNIVERSITY FACILITIES

Gymnasiums; Physical Education and Sports Facilities

The official rules of the United States Squash Racquets Association and the National Squash Tennis Association should be consulted in planning and constructing squash courts.

Rowing-Practice Facilities In certain colleges and universities, it may be desirable to construct facilities for indoor crew practice. Colleges engaging in competitive rowing will require either fixed rowing machines with accompanying mirrors to reflect the action of the rowers, or a rowing-practice tank. The rowing machines may be installed in a special activity room. If there is space underneath the spectator area in the main gymnasium, they may be installed there. In every case, the area should be well lighted and ventilated.

The rowing tank, when used, should simulate the conditions to be found in open-water rowing. The water should be mechanically circulated in such a manner as to make possible the actual introduction of the oar into the water and the completion of the stroke. The crew should be seated on a rigid platform which spans the pool at actual shell height.

All the specifications for indoor rowing equipment may be obtained from the manufacturers, and the details of the construction of a rowing tank are available through the office of the Intercollegiate Rowing Association.

Indoor Archery Range An indoor archery range is much needed in modern college gymnasiums. The popularity of the Chicago Round has made indoor ranges feasible because of the decreased shooting distances, requiring less space than formerly required for the American and York Rounds. A satisfactory indoor range should be 45 ft in width and 78 ft in length. This will provide space for 15 shooters on the line at the same time, each facing a separate target. The length suggested will provide a distance of 60 ft for the Chicago Round, two feet for backstop material, and 16 ft behind the shooting line for instructors, observers, and those preparing to shoot.

Backstops may be constructed of baled straw treated with fire-resistant materials, or may be purchased from archery equipment manufacturers. The targets may be fastened to the backstop or placed on easels in front of it. The floor in the archery room should be constructed of hard-usage materials to permit street shoes to be worn. The room should be well lighted. The target line should be illuminated by floodlights which shine only on the target area.

Research Laboratory College and university health, physical education, and recreation programs are becoming increasingly involved in research. Graduate studies and faculty research cannot thrive unless space is allocated for this work in the gymnasium building where exercise and sports areas are convenient.

Research in physical education may be of many different types. Some colleges and universities emphasize one or more areas. The research taking place in physical education programs is in the following categories: kinesiologic, tests and measurements, organic (metabolic, cardiovascular, and chemical analysis), and statistical.

A laboratory providing opportunities in the kinds of research mentioned requires a minimum of 2,800 sq ft of space for the basic equipment needed. The maximum space needs will depend upon the number of faculty and students involved and the complexity of the research program. Research laboratory space may be provided in one large room or in several smaller rooms. It is suggested that a separate

room of 300 sq ft be used for a statistical laboratory.

Steam Room Some college gymnasium facilities include a steam-bath installation. This may be desirable if supervision is present when the steam room is in use. Unsupervised steam baths or sweat boxes are not recommended.

If a steam room is constructed, a satisfactory size is 8 ft square, with a ceiling 10 ft high. A lockable door containing a window should open outward. The room should be equipped with two or three movable benches of sturdy wood construction. The steam valve used should be a type that can be set to prevent the temperature in the room from exceeding 130°.

Group Study Rooms If the gymnasium is to serve the needs of students enrolled in a major professional program, the inclusion of small-group study rooms is recommended. Study rooms should occupy approximately 150 sq ft and should be equipped with a large table and sufficient chairs to accommodate a maximum of eight students. These rooms may serve a variety of educational needs in addition to small-group on-campus study.

"In-Uniform" Study-Hour Rooms In gymnasium buildings, there is a need for rooms where men and women students who have one free hour between two activity classes may go in uniform to read or study.

The use of this room will conserve student time, encourage their reading or studying habits, and will clear the dressing rooms. Rooms for in-uniform study should be separate for men and women and should be located near the appropriate dressing rooms.

Workroom Each physical education department may wish to concentrate several work or repair functions in one or more areas according to the program and equipment and dependent upon the secretarial and office needs. Two types of areas are described below. In some colleges, it may be considered practical to combine most of the functions of these two workrooms into one plan.

Secretarial Workroom Secretaries, machines, and typewriters are assigned to some individual offices or to a group of offices, but it may not be practical to have all individual offices so staffed and equipped. Office supplies, typewriters, duplicating machines, and some other needed and desirable office machines can be concentrated in one or more department or college workrooms where services can be performed for faculty members who have limited or irregular need of secretarial help. In such a room, a workroom manager can receive assignments, distribute and allocate this work, receive it from the workers, and return it to the appropriate faculty members.

The room should have area enough to accommodate desks, tables, and cabinets, which must be planned according to the anticipated demands. Acoustical treatment and a generous supply of electrical outlets are essential to the orderly functioning of such a service area. A wall-installed washbasin and a hand-towel cabinet are important to the economy of time in the work area.

Repair and Service Workroom The need for repair and service of equipment will dictate the size of the repair and service workroom. Some departments will perform only minor repairs which can be accomplished in a small,

modestly equipped workroom or in a part of some other area already provided. Other faculties will wish to plan to repair archery-target stands, covers, field carts, and other larger pieces which require the use of tools and space. This plan to service and repair large pieces, then, will require space for the equipment to be repaired and tools with which to perform the needed repairs.

A well-equipped workroom will contain such constructional and built-in features as cabinets, a sink, wood and lumber storage racks, shelves, a blower discharge fan, a work shelf, and drawers. Many, or most, of the storage areas should be locked individually or as a group with a master key system.

PHYSICAL EDUCATION AND SPORTS FACILITIES

The following standards are recommended for consideration by those involved in planning college and university facilities for physical education, intramural sports, intercollegiate athletics, and recreation.

Type A—Indoor Teaching Stations

- Space requirements: 8.5 to 9.5 sq ft per student (total undergraduate enrollment)

- Including: Gym floors, mat areas, swimming pools, courts, etc. (adjacent to lockers and showers and within 10-min walking distance of academic classrooms)

- Uses: Physical education class instruction, varsity sports, intramural sports, unorganized informal sports participation, student and faculty recreation, etc.

Breakdown of Type A Space

- A1—Large gymnasium areas with relatively high ceilings (22-ft minimum) for basketball, badminton, gymnastics, apparatus, volleyball, etc. (approximately 55 percent of type A space)

- A2—Activity areas with relatively low ceilings (12-ft minimum) for combatives, therapeutic exercises, dancing, weight lifting, etc. (approximately 30 percent of type A space)

- A3—Swimming and diving pools (approximately 15 percent of type A space)

Type B—Outdoor Teaching Stations

- Space requirements: 70 to 90 sq ft per student (total undergraduate enrollment)

- Including: Sports fields of all types (adjacent to lockers and showers and within 10-min walking distance of academic classrooms)

- Uses: Physical education class instruction, varsity sports, intramural sports participation, student and faculty recreation, etc.

Breakdown of Type B Space

- B1—Sodded areas for soccer, touch football, softball, etc. (approximately 60 percent of Type "B" space)

- B2—Court-type areas for tennis, volleyball, flicker ball, etc. (approximately 15 percent of Type "B" space)

- B3—Specialized athletic areas for track and field, baseball, archery, varsity football, golf, camping demonstrations, etc. (approximately 25 percent of Type "B" space)

- B4—Swimming pools (included in B3 approximation)

COLLEGE AND UNIVERSITY FACILITIES

Field House

Type C—Sports Fields and Buildings; Intramural and General Outdoor Recreation Areas

* Space requirements: 120 to 140 sq ft per student (total undergraduate enrollment)

* Including: Playing fields and athletic buildings of all types; softball diamonds, tennis courts, arenas, field houses, etc. (too far removed from general student lockers, showers, living quarters, and academic buildings for use as teaching stations) (maximum distance from major residence areas—1 mi)

* Uses: Intramural sports, varsity sports, unorganized informal sports
Breakdown of Type C Space

* C1—Sodded areas for soccer, touch football, softball, etc. (approximately 40 percent of type C space)

* C2—Court-type areas for tennis, volleyball, flicker ball, etc. (approximately 10 percent of type C space)

* C3—Specialized athletic areas for track and field, baseball, archery, varsity football, golf, camping demonstrations, etc. (approximately 45 percent of type C space)

* C4—Swimming pools (included in C3 approximation)

* C5—Sports and intramural buildings providing lockers, showers, play space, office space, lounge rooms, etc. (approximately 5 percent of type C space)

Type D—Informal Recreation Areas

* Space requirements: included in C3

* Including: On-campus picnic areas (maximum distance from residence areas—1½ miles) (approximately 15 percent of total type C space)

* Uses: Picnics, outing activities (including outdoor cookery, evening songfests, storytelling, etc.)

Type E—Off-Campus Outdoor Education, Camping, and Recreation Areas

* Including: Outdoor camping and outdoor education center, off-campus golf course, university country club, etc. (maximum distance from heart of the campus—25 mi).

* Uses: Overnight camping, picnics, outing activities, camping demonstrations, golf, archery, boating, canoeing, outdoor swimming, formal classes taught outdoors.

* Estimate of space needs of this type area: It is difficult to state these needs on a square-foot-per-student basis. Such areas contribute materially to the outdoor education and outdoor recreation of both men and women students, but the many variables in climate, in topography, in distance from the heart of the campus, and in emphasis on outdoor education make a square-foot-per-student standard difficult to establish.

* It has been estimated by intramural leaders that graduate students participate in physical recreation 25 percent as extensively as undergraduates. Consequently, it is suggested that planners add 25 percent of the graduate enrollment in using the standard.

Ancillary Areas

Investigation indicates that a reasonable standard for determining the space needed for lockers, showers, towel rooms, equipment storage, supply rooms, and offices associated with type A space is a square footage equaling approximately 40 percent of the play or activity area in a gymnasium facility. As an example of how this figure may be used, assume that a gymnasium is being planned which will provide

100,000 sq ft of activity space. In other words, the square footage in the swimming-pool surface and deck, and all gymnasium floors, including high and low ceiling areas, equals 100,000 sq ft. This would mean that the square footage needed for ancillary areas would be in the neighborhood of 40,000 sq ft. Architects generally speak of the combination of play space and ancillary areas in a gymnasium as "net usable area." Consequently, the net area in the building would be approximately 140,000 sq ft.

All other space in a building, including hallways, stairways, wall thicknesses, lobbies, public toilets, bleachers for public use, custodial space, and space needed for service conduits of all types, is spoken of by many architects as "tare." The space needed for tare varies greatly from building to building, depending upon the function and architectural design. A rough estimate of the area needed for this item is a figure equal to 80 percent of the activity or play area in a gymnasium. By adding tare, ancillary, and play space, a rough estimate of the gross square footage of a gymnasium plan can be computed. This figure is helpful in preliminary discussions of costs involved.

Enrollment Relationships

When standards in terms of square feet per student are used as guides in college or university planning, it is natural to ask where the cut-off begins. At what point, from 10 students up, do the standards become meaningful? Obviously, for a college of 200 students, 9 sq ft per student of indoor area for sports and athletics would be woefully inadequate. It would not even provide one basketball court.

A university or college meeting the space standards for 1,500 students represents the minimum physical-recreation space needs of any collegiate institution. As a college or university increases in size, these standards are applicable regardless of enrollment.

Peak Load After School Hours

Through study of utilization problems at the various universities, it was found that the greatest load on facilities each day occurred between 4 P.M. and 10 P.M. In all the universities studied, either one or two years of physical education was required of all students. As long as the requirement in basic physical education is not greater than 2 years, it seems that the greatest demand for space comes after the usual school hours. This may not be true in universities which require all students to register for physical education each year they are in residence.

A few universities have dropped required physical education in the belief that this will reduce the pressures on facilities for sports and athletics. The futility of this move is obvious. In fact, the elimination of a physical education requirement may increase the demands for this type of space, since all students will then tend to use after-school hours to meet their physical-activity needs. This concentration of student activity will likely make it necessary to provide greater play and exercise space than needed for a balanced program of basic instruction, free-play opportunities, and intramural sports competition.

Application of Standards

Standards are guides for the use of planning committees and administrators. They are not substitutes for creative planning. They help

a great deal in early computations of cost estimates and are also helpful in checking preliminary drawings to determine whether or not enough space has been provided in different categories to meet the program needs of the student enrollment for which the facilities are planned.

FIELD HOUSE**Function**

The field house provides enclosed and unobstructed space adaptable to indoor and outdoor sports activities. It is not intended as a substitute for the gymnasium; it is complementary and supplementary to other facilities for indoor and outdoor physical education and recreation activities. The enclosure may also serve purposes other than physical education and recreation.

Typical functions of the field house for a college are as follows: instruction in the service program in physical education; practice for intercollegiate athletics (football, track and field, baseball, basketball, tennis, soccer, lacrosse, and other sports); intramural and intercollegiate competition; informal play; horseback riding; demonstrations and exhibitions which attract large crowds of spectators; commencement exercises; registration; and final examinations. In addition, community uses may include interscholastic games, matches, meets and tournaments; band concerts; school commencement exercises; exhibits; and mass meetings.

The total physical education program, including co-physical education and co-recreation, should be considered when plans are developed, so that facilities for activities such as tennis, volleyball, badminton, and golf practice may be provided. Unless provided in the gymnasium, handball and squash courts should be constructed in the field house. A survey of available facilities for activities common to modern physical education programs will serve to determine the number and kind of activity units to include in the field house.

Location

If needed for class instruction, the preferable location for the field house is adjacent to the main gymnasium building and the natatorium. If space is not available in proximity to the gymnasium, the field house will serve well for intramural activities and intercollegiate sports, even though it is constructed in a peripheral area of the campus. It should, however, be placed in an area contiguous to athletic fields and where parking problems are not critical.

Size

The size of the field house should be determined by careful study of its functions; consideration should be given to the size and number of groups (classes, squads, teams) likely to participate simultaneously in the program. There should be a minimum of interference of groups with each other. The area surrounded by a ¼-mi track can include the following facilities: a regulation basketball court; a tennis court on each side of the basketball court; broad-jump, high-jump, and pole-vault runways and pits; and a shot-put area.

The minimum length of the field house

COLLEGE AND UNIVERSITY FACILITIES

Field House; Dormitories

should accommodate a 60-yd straightaway for men's track plus sufficient distance for starting and stopping. A wide door at the end of the straightaway to permit competitors to run outside the field house would prevent injuries and eliminate a mental hazard where space is limited. Six regulation lanes are desirable. The track around the portable or permanent basketball floor should be of such size as to be a convenient fraction of a longer standard distance.

Balconies and Bleachers

When permanent balconies are planned, they should be constructed without supporting pillars which would interfere in any way with the playing or visual area. Balconies should be served by ramps which connect directly, or by means of wide corridors, with convenient entrances and exits. Temporary bleachers, when placed in front of and below the permanent balconies, should continue the sight lines of the balconies. Bleachers can be placed inside a $\frac{1}{4}$ -mi track on both sides and ends of a basketball court to accommodate approximately 5,000 spectators. Such bleachers should be inspected thoroughly before they are used; their capacity should never be taxed.

The field house should be so designed that normal flow of traffic will not encroach upon the activity areas. It is essential that this be done in order to avoid interference with instruction and participation and to decrease maintenance costs.

Press, Radio, and Scout Accommodations

Accommodations for reporters, sports broadcasters, and scouts should be planned in the original design. Soundproof broadcasting and television booths should be provided for these services when the field house will be used for attractions of considerable public interest.

Entrances

Entrances to the field house should be located with reference to parking facilities and traffic approaches. The main lobby should be large enough to accommodate anticipated crowds seeking tickets and admission. This is particularly important in northern climates. The lobby should be so designed for ticket selling and collecting that the traffic will flow in a straight line, or nearly so, from the entrances to the box offices to the ticket collectors. To avoid congestion, approximately two-thirds of the lobby should be planned for accommodating box offices and ticket purchasers; the remainder should be reserved for ticket holders, who should have direct access to admission gates.

Drinking Fountains

Drinking fountains should be sufficient in number and so located that they do not interfere with the circulation of the crowd.

Service Units

If the field house is adjacent to the main gymnasium building and the natatorium, the requirements for lockers, showers, and toilets can, in some instances, be reduced. An underpass from the gymnasium to the field house may be desirable in order to make the gymnasium service units available to some participants in the field house. If the field house is not adjacent to the gymnasium, consideration

should be given to the erection of a small building or a basement, simple in design, with dressing, shower, and toilet facilities, rather than using space for such purposes which might be utilized more advantageously for activity units.

Convenient and accessible dressing units equipped with chalk and tack boards for the home and visiting teams should be provided. When the field house is to be used for interscholastic basketball tournaments and indoor track meets, consideration should be given to providing separate locker rooms with adjoining shower and toilet facilities. These units could be used regularly throughout the year by intramural participants and intercollegiate squads.

It is desirable to provide passageways from dressing rooms directly to the basketball floor to avoid crowd interference.

A dressing room with adjoining shower and toilet facilities should be provided for staff members. These accommodations can also be used by game officials.

Separate toilet facilities in sufficient number for men and for women spectators should be provided in close proximity to the seating areas. Toilets should be provided near traffic lanes. Where large crowds attend games, it is advisable to place supplementary toilet facilities off the main lobby.

First-Aid and Training Rooms

A room for first-aid treatment should be provided if the field-house program is planned to attract spectators. This room may also serve the purpose of a training room for emergency treatment of participants, and the prevention of injuries.

Lounge and Trophy Room

Provision for a lounge room may be advisable after consideration of such factors as available space and funds, and the functions of such a room for clubs, members of athletic squads, letter men, officials and coaches, and visitors. An adjoining kitchenette is desirable.

Storage Space

Sufficient storage space should be provided to accommodate physical education and maintenance supplies and equipment. Supply rooms, built so that supplies and equipment may be cared for within them and issued from them, should be provided where they are needed.

Concession Booths

When the field house is planned to accommodate large crowds, concession booths should be constructed. They should be equipped with electric or gas stoves, sinks, running water, and sewer connections and should be located where they do not interfere with the normal flow of traffic.

Scoreboards and Timing Devices

Scoreboards and timing devices should be of sufficient number and be so placed that they can be seen readily by players and all spectators. They should be easy to operate and readily accessible for maintenance purposes.

Public-Address System

Provision should be made for the installation of a public-address system. Acoustical treatment of the building is desirable.

Lighting, Heating, and Ventilation

Windows should be equipped with means to prevent the interference of sunlight with player performance at any time during the day. Walls and ceilings should be light in color. Catwalks are necessary for servicing the ceiling lights, spotlights, and net.

Condensation problems should be given major consideration, particularly where there are extremes of temperature, where sprinkling of surface or dirt areas is required, and where large crowds witness events in the field house. As a means whereby some of the excess condensation may be reabsorbed, the building should be heated by the circulation of warm air in addition to fixed radiation. Adequate means should be provided to supply fresh air and to exhaust foul air. The walls inside and outside should be impervious to vapor pressure. Technical heating, ventilating, and lighting problems should be referred to a specialist.

Floors

The floor of the field house should be of an all-weather-resistant construction. Rubber asphalt and several patented rubberlike synthetics should be considered. A portable wood floor for basketball may be used. Dirt floors are not recommended.

DORMITORIES

Area Requirements for Student Room Furniture

1. Furniture sizes and use spaces are the average for existing furnishings.
2. Each furniture layout assumes the item(s) placed along a wall.

Use Space The use space of one item may overlap the use space of another, but no use space should overlap an adjacent item of furniture.

Fig. 1

Designations An item of furniture automatically requires additional space around it to make it use possible. This space should be allowed for in the planning of the room.

User Requirements, URBS Publication 5, University Residential Building System, University of California, Berkeley, Calif., 1969.

COLLEGE AND UNIVERSITY FACILITIES

Dormitories

Fig. 2

Planning Studies—Single and Double Rooms

General

1. Room dimensions must accommodate:
 - a. Furniture sizes and design (wall mounted, freestanding)
 - b. Furniture use spaces
 - c. Combination of furniture items
2. Room size (and shape) will affect two levels of possible room change:
 - a. Adaptability of furniture arrangements
 - b. Divisibility of spaces—physical or visual separation of activities

Room Areas

1. Definition of terms used:
 - a. *Minimum*—access to furniture items; overlap of items and use space; some restriction in the use of furniture.
 - b. *Optimum*—no overlap of items and use space
 - c. *Generous*—beginning of space divisibility
2. Single Rooms
 - a. Minimum recommended area—90 sq ft
 - b. Optimum recommended area—110 sq ft
 - c. Generous recommended area—120 sq ft

3. Double rooms with bunked beds

- a. Minimum recommended area—140 sq ft
- b. Optimum recommended area—160 sq ft
- c. Generous recommended area—180 sq ft

4. Double rooms without bunked beds

- a. Minimum recommended area—180 sq ft
- b. Optimum recommended area—220 sq ft
- c. Generous recommended area—240 sq ft

Offset Single Rooms

1. Conclusions

- a. The area of the room with an offset may be comparable to a rectangular room with little or no loss in the adaptability of furniture.
- b. If dimensions of the room and furniture sizes share a common module, an offset room may have a slightly greater amount of furniture adaptability than a rectangular room of equal area.
- c. In an offset room, the controlling object is the bed in determining the proportional areas of the two sections of

the room. If it is desirable to move the bed from one section to the other, the two sections will be approximately equal in size. If it is not desirable, the interchangeability of other pieces of furniture will control the dimensions and size of each section of the room.

- d. An offset room will increase the possibility of space divisibility. In a rectangular room, the items must create the space; in an offset room the walls divide the space.

Student Rooms The student room is the smallest element and the basic space in the housing facility. It is the core environment of the student who spends many of his waking hours here (undergraduate girls, 8 hr; boys, 6 hr). In this space the student studies, sleeps, dresses, and socializes. He stores all of his clothes, books, and personal possessions here except for non-seasonal clothing and larger-size sports equipment. In a very real sense, it is here that his identity within the university is established, since it is the only space on campus which he himself can control in any way.

1. *Study.* Individual study is accomplished within an amazing spectrum of activities. It takes place while standing, walking, sitting, lying, singing, whistling, eating, drinking—alone or with another person. Few participate in group studying.

People study at different rates. Some subject themselves to long periods of monklike concentration; others apply themselves for relatively short periods interspersed with intervals of social or recreational activity. The individual prefers to study in his own room and, for intense study, by himself. For this type of study, the roommate must be elsewhere.

The desk apparently is used for reading only in cases requiring extensive note-taking or use of several reference sources. Otherwise, it is a repository for study and personal equipment including typewriters, calculators, drafting equipment, radios, and phonographs. Yet it does not have the height accommodations or acoustical padding needed to use these materials quietly and effectively. Its length is inadequate for any use—the 42 in. standard desk is overtaxed with books and writing material [as well as] personal paraphernalia. The space requirements for multiple references, collation of materials, or large belongings create overflow onto the bed or floor. Consequently, work is often done on the floor of the room, particularly if it is carpeted, and on the bed.

Sometimes an apparent student idiosyncrasy has a real functional basis. Many students were observed typing on the floor when an adequate table was available. The students then demonstrated the drumlike sound of the unmuffled typewriter which conflicted with their roommate's sleeping. Students often used the corridors and bathrooms as study spaces when typing and study rooms were missing or occupied and roommates were sleeping.

Bookshelves are generally inadequate in size and length. Moreover, the shelves are usually in places of difficult access and are poorly illuminated. There is a need for more shelves, preferably adjustable and flexible as to placement.

Built-in furnishings are resented because their rigidity impedes both individual living and study habits. Students are forced to supplement the university furnishings with such things as orange crates to create an individual study environment. The results may appear cluttered to some, but they accommodate the occupant. Clearly then, a book, pen, reading light, straight back chair, and a 42-in.-long desk

COLLEGE AND UNIVERSITY FACILITIES

Dormitories

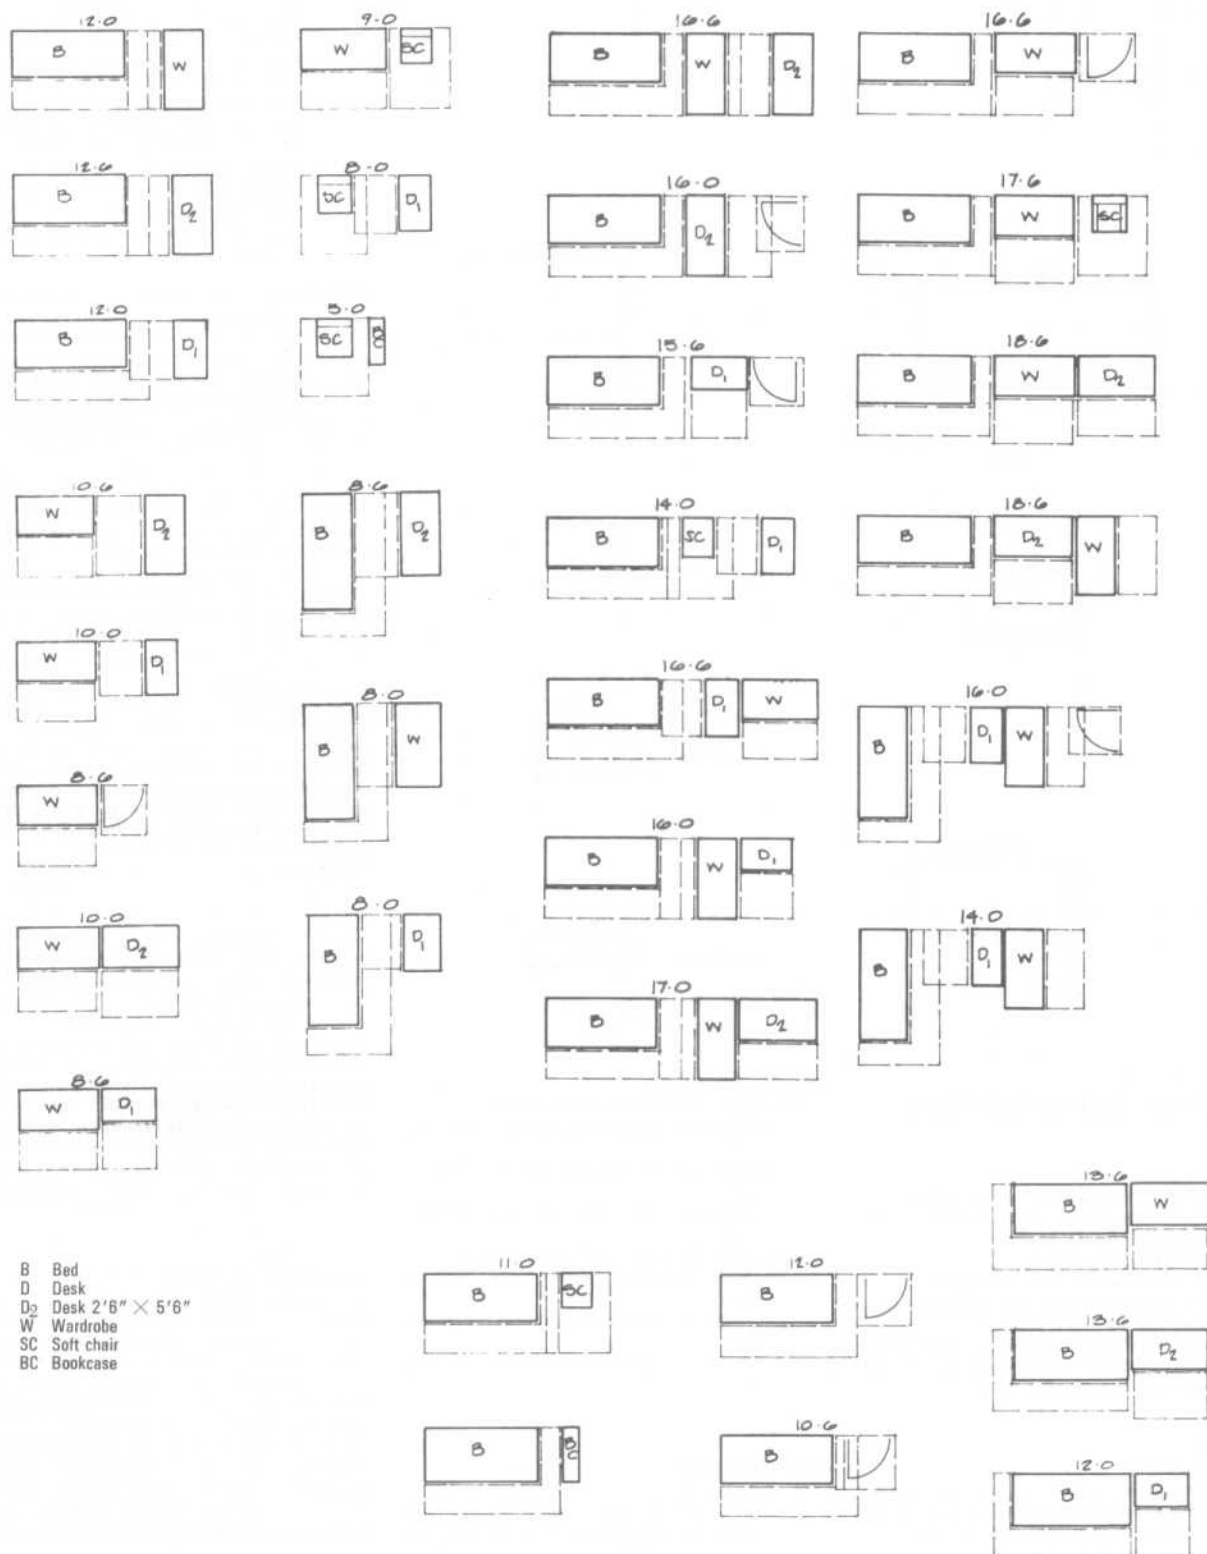

Fig. 3 Examples of furniture layouts depicting some possible arrangements involved in the planning of the student room.

COLLEGE AND UNIVERSITY FACILITIES

Dormitories

Fig. 4 Diagrammatic arrangements rectangular rooms, single rooms.

constitute less than the optimum answer to the study problem.

The telephone is a most important tool to the student. Its use is restricted only by the university's ability to provide an individual instrument and the student's ability to pay the toll. The telephone is finding increased use—both as a study and a social aid.

The tremendous and continuing advances of the electronics industry are only beginning to be noted in the educational sector. Although the student of today is required to attend unilateral communication lectures in large halls, the student of tomorrow may view the lecture on TV in his room, coming out for seminars or laboratory sessions. Future student housing must accommodate this.

The students of all campuses could simultaneously be able to receive the lecture of one outstanding professor or professional team. Much of this communication will be at the discretion of the student. It is but one indication of the growing importance of the student room as a study aid. Only the provision of conduit

access is needed to expand the horizons of the student room beyond imagination.

2. *Sleep.* The student's pattern of activity is rarely consistent; he may sleep at any time of the day or night. Two occupants of a room very rarely follow the same schedule. Exams and social activities modify their patterns even more extensively. It is the varying patterns that present conflicts in multiple-occupancy rooms. Interesting improvisations—hanging blankets, relocated wardrobes and beds, and stacked dressers—were observed in situations where one student wished to study while the other slept. Perhaps beds with suitable acoustical light-separation screens could be one answer; single-occupancy rooms would be better.

Present provisions for sleeping range from the studio bed in single rooms to bunkable beds in multi-occupancy rooms. Beds acquired a decade ago are increasingly limiting to the succeeding generations of taller students. Reading is more often done in the comparatively relaxed attitude of the bed or easy chair. However, the bed is seldom designed to pro-

vide the slight slope for proper sitting; some adjustment therefore is necessary. Beds could be made to resemble couches and have a mechanism allowing a shift from sloping for sitting to level for sleeping position.

3. *Socializing.* The student's room has always attracted social discourse. With more liberal rules, the student's room becomes more of a social center for both sexes. The student room, however, with its split emphasis of study-sleep, presents difficulties as a social environment. The bed is the chief offender. The bed as a bed conjures all sorts of social problems in intervisitation. A bed with cushions or pillows tossed about is not acceptable because of the difficulty of sitting upright comfortably. Its conversion to a sofa, with its contributions as a living room furnishing, is most desirable—not to mention its more comfortable use for multiple seating.

Clothes and storage of personal possessions are also a bedroom symbol. Closets look like closets; dressers look like dressers. Contemporary furniture designers, however, have provided storage units for studio-apartment [which are] quite acceptable as living room pieces. Such pieces have yet to make their appearance in student rooms. It should be possible to have either intimate conversations or sessions with a number of additional individuals within one's own private room. The bed, hard and soft chairs, and even a desk top may be brought into use as sitting surfaces to accommodate a congenial group. The space should be such that furniture can be quickly arranged to make group conversation easy.

4. *Dressing.* The concentration of clothes storage in the student room not only precludes its use as a social environment but also restricts its use for dressing. One study discloses that the normal 4-ft closet and five-drawer dresser just satisfies the male student, and it provides only half the female student's storage requirements. Both sexes require differing volumes and types of storage. Smaller combination-storage units might well accommodate student preference and allow flexibility of room arrangement.

Types of Spaces

1. *Single rooms.* The single room provides controlled privacy for its occupant with respect to all other students. It may open directly to a corridor and thus provide complete privacy coming and going, or it may be part of a suite or apartment. Privacy for sleeping can be controlled if adequate acoustic separation between adjacent spaces is provided.

The single room should be arranged suitably so that it is possible to study effectively with an invited second person. In addition, the student should be able to play the radio, phonograph, tape recorder, or quiet instruments and to indulge in reasonable recreational activity without creating an acoustical problem for his neighbors.

One authority believes the single room is "unlikely to be really humanely satisfactory if it is less than 120 square feet. The furniture should be movable, not fixed, to allow the student to organize his own environment."

2. *Split double rooms.* The split double room provides the social contact obtained by two students sharing a common space but, at the same time, recognizes and solves the problem of conflict of interest in the student's social and study activities. The split double room consists of two spaces with a connecting opening. When connected with a door, there is a degree of acoustic privacy. Without a door, the ar-

COLLEGE AND UNIVERSITY FACILITIES

Dormitories

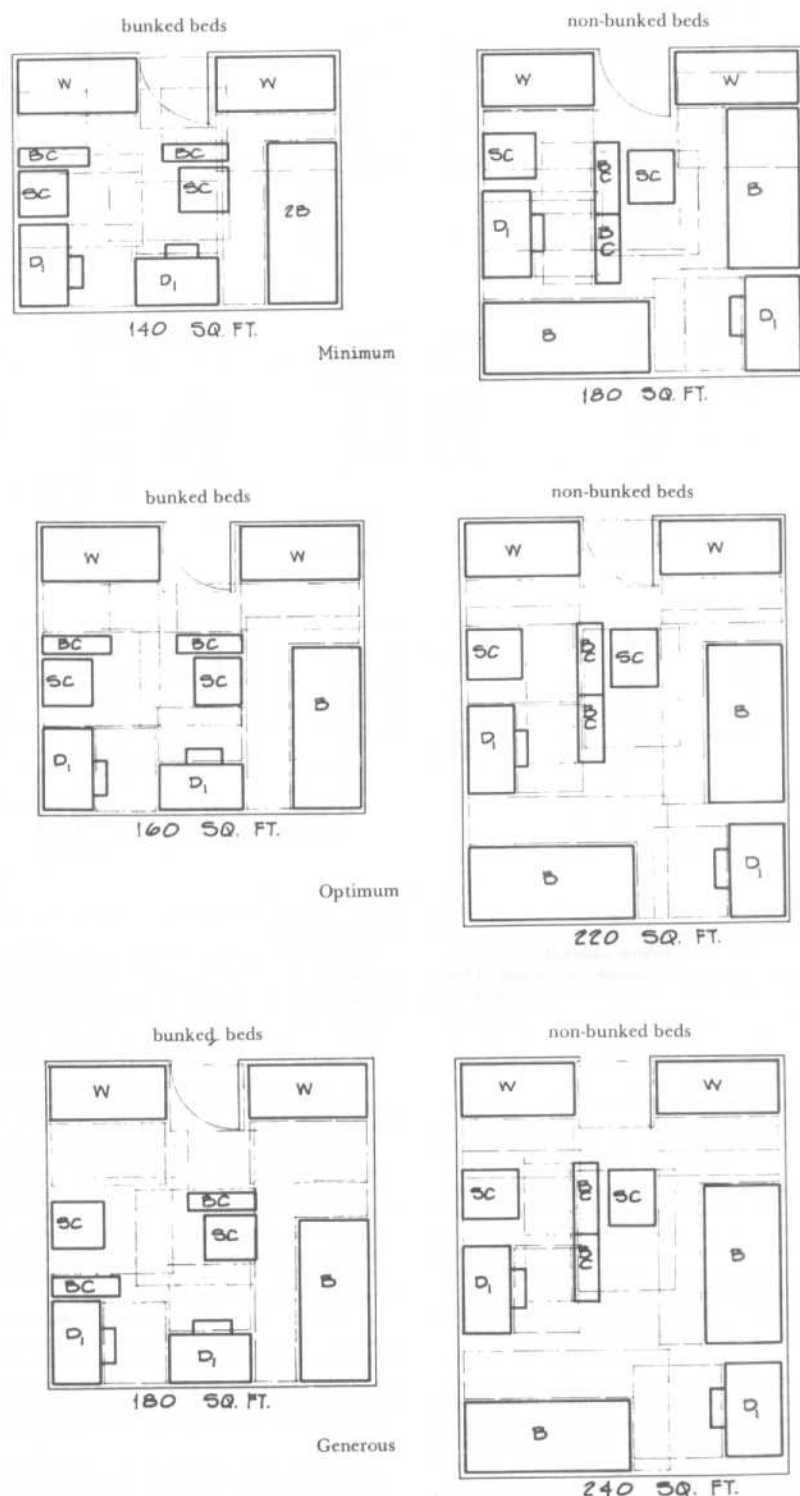

Fig. 5 Diagrammatic arrangements rectangular rooms, double rooms.

arrangement provides only visual privacy and shielding from illumination sources. The provision of two spaces makes it possible for one student to sleep while the other studies or talks with friends.

The best arrangement would permit the students to treat each of the two spaces as a single

room with direct communication between them. Then the spaces may be separated on an activity basis, with the desks, study, and living facilities in one space and sleeping and dressing facilities in the other. When one of the two spaces is large and the other small in size, the students live together much as they would with-

in a traditional double room. Where the habits of two students come into conflict, the second smaller space can relieve the situation. For example, the second room can provide for a late-hour study station. This type of arrangement will not necessarily suffice to provide the appropriate separation between social and sleeping habits, but it may do so if the smaller space has sufficient room for an extra chair.

If two students must share space, the split double represents an optimum arrangement, because easy choice exists for privacy or sociability.

Here again, the space with the two beds should have the atmosphere of a sitting room so that one is not consciously in a bedroom.

3. *Double rooms.* The double room is the present standard in student housing, largely because of the tradition and economies it presumably brings to initial construction costs. This economy is deceptive, however. Since these rooms irritate their inhabitants because of lack of privacy and quiet and because of insufficient study and storage space, it becomes necessary to provide typing rooms, individual study carrels, and large public lounges (furniture showrooms). These factors should be considered when citing the economies of the standard double-room residence hall.

Fig. 6

At present, the area of a double room varies between 145 and 250 sq. ft. Within these areas, possibilities for alternative furniture layouts and room shapes are particularly important. Some room configurations make possible the separation of the two students in their study activities; others situate the desks in parallel arrangements for study. The use of movable wardrobes to shield the beds from desks provides the degree of separation between activities within a room but reduces the apparent size of the room. Wardrobes which are grouped to provide dressing alcoves or to line corridors remove valuable space from the room itself. If double rooms are to be provided, there should be sufficient area to convert them into split-double, single, or other types of rooms in the future. *More than enough conventional double facilities already exist on most campuses.*

4. *Triple room.* This form has been popular with some students on a small number of campuses. Where this arrangement has been used with movable furniture, the extra area provided in the single space has made possible a large number of different space arrangements. The resulting individuality of the layout of the room would appear to be a major reason for the popularity of such spaces, since some students do seem to prefer a three-student to a two-student room. The triple room, however, tends to breed more serious interpersonal problems.

5. *Four-student room.* Four students sharing one room have the same problems as the students sharing double- or triple-occupancy rooms. There is a slight advantage in that the space is usually large enough to be subdi-

COLLEGE AND UNIVERSITY FACILITIES

Dormitories

vided by wardrobes, lightweight partitions, and other elements.

Although few students would choose to live in a single space with three other strangers, four friends might choose to be together and succeed at it if provided sufficient options for the disposition of the space and for the appropriate screening of different activities.

Large numbers of students may share a space, but more than four require that separate adjacent spaces be provided for conflicting activities. At this point, one must consider the suite plan.

6. *Suites.* A suite is an arrangement in which four or more students share the total space in single and double rooms, with or without a bathroom, and at least one extra common space. In this way, the group of students working and living together have at least one space under their own control which may be used for any of the three major facets of room life: sleep, study, or social activities. "The major value of the suite plan is the opportunity it affords for closer student association and the freedom it gives students using the various spaces as they wish." The common space within a suite (1) reduces some of the pressures felt by two students trying to share a single room; (2) provides for social activities as does a residential living room, and (3) includes in social activities those students who might not have direct or easy association with other students.

The sharing of a fair amount of space by a group of students makes possible a variety of usage patterns and provides considerable flexibility in room rearrangement so the space may be organized in the best possible way.

Typical patterns are a common room also used as a study room; one room used only for sleeping, with separate rooms for study and social purposes; and four single rooms or two double rooms with a common living room.

Suites composed of single rooms rather than double rooms increase the potential for privacy. However, if one desires a separate room for each student, additional square footage above that normally required for four students will be necessary. This space can be regained through a reduction in the large lounge spaces on the ground floor.

Another way to obtain sufficient area for a suite is to incorporate some corridor space in the common room. Corridors may not be necessary for a four-student suite; therefore, this approach works best when perhaps eight or ten students share a suite. A major problem in optimum use of the common room of a suite concerns doors that do not provide sufficient acoustical separation between the common room and the individual's room. In such a case, spaces for study outside the suite become necessary.

Bathroom facilities pose one of the major questions in the design of suites: should these facilities be available just for the suite or for a larger group of students? Although initially it is less expensive to build gang facilities for larger groups, long-term economy can be obtained by providing residential-scale bathrooms for suites wherein students, instead of maids, clean the facility. The reduction in maintenance requirements will more than amortize the increased first cost of smaller bath facilities, while also considerably improving the human quality of the housing environment for the student.

Suites must also be considered for the social impact resulting from them. Students developing a strong social life around the activities of their suite may have less incentive to make friends outside their circle. Objections might be

Fig. 7

posed for this reason, especially in regard to freshman students who desire maximum opportunities to meet fellow students.

Another problem in suites composed of four to seven students is the possibility that strong friendship patterns may have a detrimental influence on a student's academic life. The peer group pressure to go out for coffee or a hamburger is quite strong on one out of six. Riesman notes this "encapsulation." One size of an encapsulated group has been equated with the six occupants of an automobile. Therefore, the organization of space into suites must be such that the students in different suites may interrelate. If, for example, three suites of six students share a larger living room so that a group of eighteen have something in common, it is quite unlikely that a small group desiring a coffee break could interrupt the study pattern of the other eleven. More likely, they will find only one or two others willing to go along.

The shared living room also provides a larger base for friends and tends to reduce stress. The value of grouping students into a suite where an ordered pattern of relationships may develop (first with a roommate or perhaps with two or four additional students and then with a larger number) provides some balance in the way outside attachments are formed. Such relationships are not well studied at this time and the patterns of change in the future may be very considerable. *Therefore an approach to the use of suites should leave open the maximum number of options for future living patterns.*

Within the suite it is important to organize the common spaces so that privacy is maintained between the sleeping rooms and the bathroom. Problems occur where the common room(s) in a suite may be open for coed activities and it is necessary to pass through the

common area when going between one's room and bathroom.

With eight or more students in double rooms, more than one common space in a suite is required. At least one separate study as well as a social room should be provided to accommodate privacy for study and typing late at night and the noisy social sessions that inevitably occur within a suite. Obviously, single rooms designed so that privacy may be maintained represent the most ideal solution.

If the suite is entered through a common space, this space is useful only for purposes where quiet and privacy are not essential. Attempts to provide a combined living-study room in the suite are not successful because students soon revert to using their bedrooms for study. The suite telephone must not interfere with study activities.

7. *Apartments.* An apartment differs from the suite in providing a kitchen. It may consist of single or double rooms built around common spaces as in a suite, or it may have a number of students in a sleeping room with the other spaces in common for social, dining, and study purposes.

A consensus of opinion among students indicates that three to five single students form an optimum group for apartment living. This number tends to work well in arranging cooking chores for the week, with weekends left on an individual basis. With more than five students, assignment of cooking chores becomes difficult. Indiana University and Michigan State University have extremely popular facilities accommodating four students.

Some students believe they get better food at less cost if they do their own cooking and shopping. Therefore, the apartment requires adequate food supply capacity to handle a

COLLEGE AND UNIVERSITY FACILITIES

Dormitories

week's supply of groceries. The apartment's dining area must be of a size to permit the occupants to have dinner guests.

Experience indicates that most students living in apartments tire of the responsibility of cooking and cleaning. It would seem appropriate to develop central food service to relieve apartment groups of the cooking chores while still retaining the benefits of apartment-type living.

For example, Indiana University has two living groups of 60 students having common kitchen facilities with another residence hall which provides the food service of the small living unit. Trolleys containing food for 60 students are wheeled from the central kitchen to the serving kitchen within the living units. All services and cleanup are then handled by the living units at a very considerable savings in cost. These two facilities are the most popular ones on the entire campus.

Much of the attraction of the apartment is its comparative freedom from behavioral control, particularly in regard to coeducational activities. This does not mean complete relinquishment of responsibility on the part of the university but rather the more positive recognition of the student's adult qualities.

Students living in apartments tend to develop a very close relationship with those sharing the space. It is a pattern perhaps more appropriate for upper division and graduate students than it is for lower division students. These students have developed a range of acquaintances on a campus and now are interested in cultivating specific friendships. Apartments, like suites, can be grouped to provide activities through combined use of spaces for recreation, study, and social affairs so that a wide range of friendship is possible.

Since the key difference between the suite and the apartment is the kitchen, provision should be included in suites for a plug-in kitchenette so that conversion from suite to apartment may be accomplished quickly. This will enhance flexibility of use during the summer sessions for conferences involving families or for foreign students.

Space Allocation

1. *Dimensions of student rooms.* Rooms of minimum size cause many complaints from students; this was reflected in both the URBS and another recent study. The situation has changed a great deal in the past 25 years. Stern Hall at Berkeley was built in 1940 and allowed 480 gross sq ft per student with 250 sq ft in the student room. Present rooms of 85-95 sq ft per student create serious problems of constriction.

Built-in furnishings compound this problem by preventing an expressive control by students of the layout of their rooms. Movable furniture, in most instances, would not alleviate the problem because the small room size dictates only one possible arrangement. The need for expression is so important to the student that he sometimes resorts to an irrational layout, such as placing the bed across the door opening, in an effort to control his environment.

The allocation of space will be the decision of the campus. Adequate space allocation within the student room must have first priority so that enough space is provided to allow both immediate individual expression by the student and future arrangement by the university.

Several studies have recommended that a single student room of rectangular shape contain 100 to 115 sq ft. The rationale for this recommendation is that a room must contain enough space to provide the student with (1)

COMMON LIVING ROOM, TWO DOUBLE ROOMS.

COMBINED SOCIAL AND STUDY ROOMS,

SEPARATE ROOMS FOR STUDY, SLEEPING,
AND SOCIAL.

Fig. 8 Suite organization 1.

the furniture he needs, (2) space for the use and service of this furniture (make beds or open drawers), and (3) possibility of a variety of furniture layouts.

Environment

1. *Thermal.* Student rooms require an appropriate thermal environment for the functions carried on within them. The environment is affected by temperature, ventilation, humid-

ity, radiation, and the quality of air produced by filtration.

The thermal system in student housing allows for individual requirements and the wide range of conditions which personal preference may demand. In a mixed community of smokers and nonsmokers, it is important that the air be kept moving and clean, particularly in student rooms, interior spaces, lounges, and study areas. Because of variations in student hygiene,

COLLEGE AND UNIVERSITY FACILITIES

Dormitories

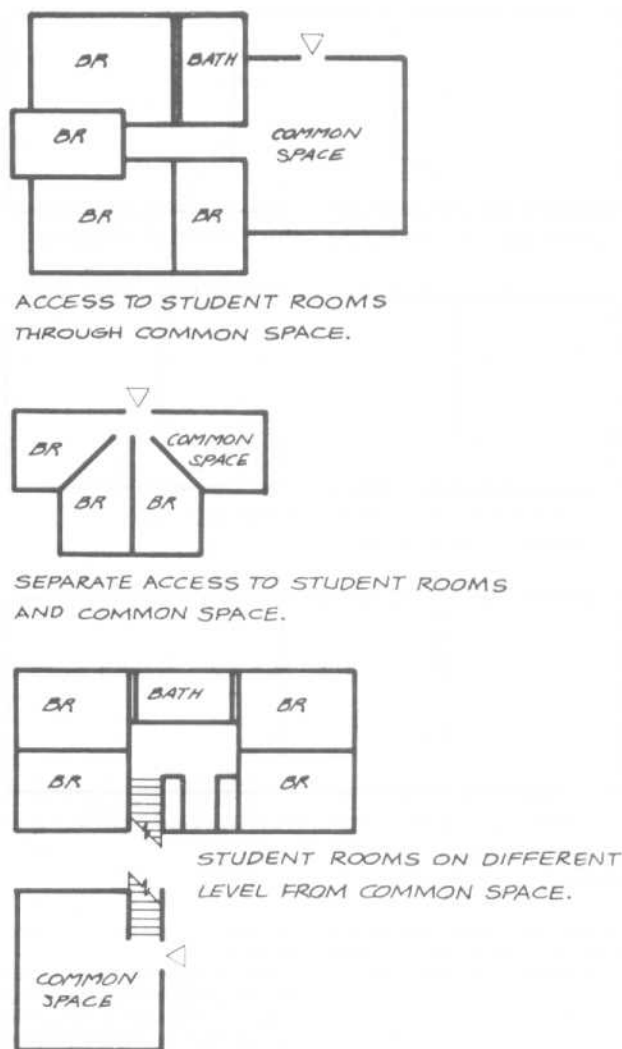

Fig. 9 Suite organization 2.

separate ventilation of individual spaces is required, especially in the more athletic men's halls. The odors in many residence halls were found by visitors to be "overpowering."

Although conventional air conditioning is more economical within a sealed space, it is important that students be able to open their windows to enjoy the soft, fresh morning and evening air, and in the lower-height buildings to enjoy communication (but not access) through an open window.

2. *Lighting.* The quality of lighting in student rooms is determined by the quantity and brightness of both the light sources and their general surroundings. High illumination levels are appropriate to study; lower levels to social functions. In the daytime, natural daylight may provide much of the necessary illumination it is to be done, but the brightness contrast between the work and its surroundings must be at a minimum.

Lighting sources in student rooms should be integrated with the movable furnishings. This tends to minimize maintenance and fix the light's proper level. Light for reading in bed, in-

cluding a reading light for a bunk bed, is necessary. Because of the highly individualized nature of activities performed in student rooms, light from a number of well-placed but relocatable point sources is far more useful than light from one central source.

3. *Acoustics.* Quiet is the most desired characteristic of any living arrangement in the opinion of students, so acoustical considerations are of great importance. Fundamental to providing quiet environments are walls, floors, windows, and doors providing adequate reduction of sound from adjacent activities. Doors do not facilitate noise reduction. Since standard doors are poor in acoustic performance and high-performance doors are too expensive for student housing use, a solution isolating noise at low cost will have to be developed. The best inhibitor of noise is good planning of the relationships between rooms. Wherever possible, social areas should be isolated from student rooms by at least two doors.

4. *Color, texture, materials.* Materials presently used are hard, unyielding, and chosen for their durability and ease of maintenance. However, those used invariably lead to a depressing, sterile, institutional appearance.

The student's need for expression and the

university's need for ease of maintenance need not conflict. Walls can be covered with safe, removable wall-covering panels that provide the student with unrestricted freedom of color and decoration. At the same time, these wall coverings can still protect the underlying materials to the university's satisfaction. It should be possible for the student to roll up his wall coverings at the conclusion of use and use them again elsewhere if desired.

Such panels would allow women students to compensate for the universal institutional aspect of student housing by softening the environment through the use of feminine colors, textures, and materials.

It was observed that in rooms with hard walls, pinup materials are often fastened to the softer acoustical tile ceilings. Resawn wood wall panels, however, would permit unrestricted tacking up of decorations.

It was noted that carpeted residence halls are far more quiet and that the behavior of the student was more adult. Since many study and social activities are performed on the floor, the comfort and quiet provided by carpeting are quite desirable.

5. *Appliances.* A revolution in the design, production, and marketing of economical personal appliances has been occurring in recent years. As a result, the number of electrical appliances brought by the student to college invariably exceeds the number anticipated by the designers of present-day residence halls. Consequently, this has precipitated problems of general safety, fire hazards, intolerable odor, noise levels, and frequent interruption of electrical services.

Another significant new trend is in the personalization of entertainment and cultural media; tape recorders, radios, phonographs, and miniature TV sets are within the economic reach of most students. The transistor radio permits the student to listen to the world beyond the campus even as he walks from one class to another. Similarly, the personal, transistorized TV is making the TV room out of date, just when most residence halls are specifically providing such space.

Hot plates, coffee pots, and popcorn poppers are sources of potential fire hazards and odors. At the minimal level of food service, there is need for facilities enabling students to make their own coffee. This requires but an appropriate surface and an outlet, with the student providing the appliance. At the next level is a desire for cold drink storage facilities. Students will sometimes buy old refrigerators—often hazardous and awkward in size and arrangement. The idea of partitioned refrigerators, as in English residence halls where students may keep track of their own belongings, would seem to be a good solution. The minimal cooking done on a hot plate introduces the need for clean-up facilities. The sink becomes necessary; the problem becomes one of the minimal kitchen facility—a project expensive enough to require careful consideration of how many students it is going to serve. Where such kitchens are provided in addition to full food service facilities, they must inevitably be few and far between. Women are far more interested than men in such a facility.

Television, radios, tape recorders, stereos, movie projectors, and phonographs create disturbing noises for others. These require, in most buildings, extensive and expensive noise abatement policing. The better solution to the problem of appliance noise, previously mentioned, is good planning for adequate isolation between rooms.

Most of all, new buildings must recognize the evolution of electrical use by providing ini-

COLLEGE AND UNIVERSITY FACILITIES

Dormitories

tial high capacity with provision for easily adding to that capacity with minimum disruption.

Facilities

1. *Bathing.* The gang bath is one of the most persistent features of residence halls. It has been defended on the basis of economy and its contribution to socialization.

Certainly, the initial construction cost of one central gang bath is less than that of smaller installations in several locations. It is also evident that when a bathroom serves more than a few students, maintenance becomes nobody's business but the university's; the student does not realize that he is paying extra for the university's maintenance of the gang bathroom. The initial extra expense for smaller baths will actually result in long-term cost savings if the students themselves maintain the smaller bathroom, because it eliminates the need for maid service throughout the life of the building.

Another economic factor against the gang bath is its inflexibility. Residence halls with gang baths are far less appropriate for participants in conventions, reunions, and institutes where families or both sexes are involved than are areas with smaller baths serving a few persons.

2. *Dining.* There is universal agreement that the single, large rooms for hundreds of students is not the satisfactory solution to the

problem of student dining facilities. Although the large kitchen with its extensive equipment, service line arrangements, and building area is the most economical and efficient method of food preparation, the one large dining room for all students negates a congenial atmosphere for social interaction during mealtime.

Dining facilities that combine the best advantage of the large kitchen—efficiency, economy, and flexibility—while at the same time providing a pleasant and social dining environment can be built. Proper planning permits large central areas to be divided by movable walls into smaller or intimate dining rooms. The walls can be moved when a large scale is needed for social events such as dances, etc.

Food preparation in student rooms presents a safety and sanitary problem, but the need for between-meal snacks can be solved independently of the central dining room. Students can be accommodated by automatic vending machines located at strategic points in the residence hall or by provision of facilities in which they can prepare snacks themselves. Student food preparation problems cannot be solved by unenforceable prohibitions but only by construction of appropriate areas with automatic cooking devices and controlled food storage facilities.

3. *Recreation and social activity.* Assimilation into the student society is the foremost concern of most new students. Recreational

spaces and facilities are important in providing environmental support to the personal interaction of students, both new and old, since academic assimilation and involvement are not restricted to the classroom or student room. However, care must be taken in the areas programmed for recreation so that they truly accommodate the intended activities. Otherwise, the spaces will fail to accomplish the intended purposes. Evaluation of the success of social spaces in meeting their intended needs indicates that a variety of smaller spaces are likely to be the most popular and useful.

Student complaints are universal concerning the typical residence hall's main lounge. It has been relatively unpopular with students because of its large size and lack of individualized space. The tendency is for this space to become monopolized by one small group, or even one couple, making other individuals or groups hesitant to intrude. A recent study shows that 32 percent of student residents use the lounges less than once a week and that 36 percent of them use the lounge only one to three times a week. The lounge fails because it cannot simultaneously accommodate incompatible activities. The piano, TV set, and sofa are not appropriate companions. The main lounge, furnished with expensive, hotel-like furnishings, is usually designed, and is mainly suited, for large, quiet groups. It is seldom used by the students for entertaining friends.

The suite living room can accommodate both quiet and active uses, although conflict occurs when the space attempts to serve socializing and study.

Small "date" rooms, as observed on some campuses, are popular when not overly supervised. However, date rooms seem to be an artificial solution to a problem better solved by a wider range of social rooms.

Television rooms are losing their effectiveness as social centers because the diminishing cost of television sets makes it possible for students to have individual sets in floor lounges or in their rooms.

Spaces allowing vigorous activity are important to all students, especially men. At present, such activities (if provided for) are usually located in drab, ill-equipped basements. In those residence halls where suitable spaces are accessible to food sources and open occasionally to both sexes, they are very popular and used continuously.

The comparison of expenses for furnishings between main lounges and recreation spaces shows the latter to be less expensive. Since main lounges are infrequently used, money spent on them is largely wasted. To provide more useful variety than is now available, the question of area allocation to main lounge—recreational spaces should be carefully considered.

One way to provide close at hand recreational space is to equip the rooftops of residence halls for recreational activities. Problems arise in regard to construction, cost, controlling vents, and flues; nevertheless, rooftops are a desirable location for many activities.

Another important form of recreation, but seldom provided for, is student hobbies. The mess and equipment involved in many hobbies suggest that perhaps older utility buildings on campus could provide spaces for these activities. It is more difficult to foresee the needs of hobbyists and expensive to introduce into residence halls the sufficient acoustically isolated spaces for them.

4. *Cultural.* Residence halls can participate in the overall academic environment of the university with the inclusion of facilities for library, music, and discussion. It is part of the

Fig. 10

COLLEGE AND UNIVERSITY FACILITIES

Dormitories

job of housing to smooth the transition from green freshmen to sophisticated seniors. At Harvard University, house libraries relieve some pressure on central facilities, creating a sense of academic community as well as making books more readily available. Inexpensive paperback libraries are quite adequate for providing both stimulating and enjoyable reading materials within a residential atmosphere. Eventually these libraries will include random-access listening stations; it is therefore advisable to initially provide adequate distribution access into the structure.

Music rooms can also serve as tape and record libraries, although the centrally located equipment will be used less frequently as more students can afford their own equipment. All music involves a noise factor which must be considered.

Formal academic classes in residence halls present difficulties in mechanical services and density beyond the capability of most residence hall structures, but informal classes and seminars can be successfully held in the social spaces in the hall.

5. *Service and storage.* The university must provide facilities for (1) maintenance of buildings, (2) the mechanical and electrical equipment, and (3) overflow storage from student rooms.

Increasing affluence of students and the growth of disposable articles have increased space requirements for efficient trash collection and removal. Trash chutes, central collection facilities, and dumping trucks are required to handle present volumes of trash. Too often this involves the ugly exposure of the trash while awaiting collection, as well as the considerable fire hazard.

Efficient maintenance of electrical and mechanical systems requires easy access without the invasion of student privacy. Equipment should be so located.

Out-of-season and seldom-used student property is usually stored in inexpensive areas of a building, but these are often the least accessible. This situation could be relieved by more adequate storage provisions in the student room. Student and service storage should be in separate areas and away from heavy traffic areas such as laundry and recreation rooms. Bike shelters, surfboards, skis, and scuba gear present spatial storage problems that require careful consideration. All student storage areas must be lockable.

6. *Circulation and interrelation of spaces.* The residence hall is a social organism. The relationship of student rooms one to another and to the public and service rooms make up a total environment most conveniently studied as a hierarchy of spaces. The hierarchy is determined by the student activities and the physical characteristics of the building. Following is a hierarchy of typical unit sizes in university housing:

Student unit	Students
Room	1-2
Suite	4-12
Group	16-24
House or floor	48-72
Hall, building or college	120-800
Complex of halls . . .	1,200-4,800
Campus	12,000-27,500

Unit size is defined by building spaces, activities related to space, and by agents of regulation and control. For example, a number of rooms served by a bathroom constitutes a suite, group, or floor. A number of rooms under the direction of a resident assistant will estab-

lish a unit. All the rooms on one floor having common access and services may also be considered as a unit.

The predominant traditional pattern is the familiar double-loaded corridor arrangement wherein the unit is one floor of a residence hall. This plan offers easy control opportunities. With a group of 48 to 72 students, it facilitates the organization of intramural and academic activities. Another source of group size derivation is the optimum number sharing bathroom facilities.

Efficient space utilization requires that the circulation area comprise the smallest possible percentage of the total area. Studies of existing student housing show the efficiency percentage varying from 7 percent to 25 percent. Although it is advantageous to reduce circulation areas, building safety codes prescribe minimum areas and arrangements. Corridors which are mean, cramped, and possibly dangerous in an emergency are not acceptable.

Economy is the obvious feature of double-loaded corridors because core plans require more circulation area. When each student has a single room, economy of circulation space is difficult since each room must have a window on the periphery of the building. This arrangement, in its simplest configuration, requires extremely long frontages. Irregular building configurations to reduce corridor space must be considered in a cost context also.

Elevators for freight and disabled students are useful in all buildings. In high-rise buildings, passenger elevators are essential, although they tend to make insular entities of each floor. This problem can be reduced by skip-stop elevators stopping at unit lounges linking two floors. The initial expense of good elevators is not offset by cheap ones requiring much maintenance. Competent servicing can be provided by including maintenance contracts in purchase agreements. The better service an elevator gives, the less likely it is to be

COLLEGE AND UNIVERSITY FACILITIES

Dormitories

abused. Elevator switches, as common targets of student pranks, must be tamper-proof. Escalators are too expensive and have far too great a passenger capacity to be viable alternatives in residence halls.

The location and intensity of such fixed facilities as baths, stairs, and elevators are the main inhibitors of future rearrangement. The URBS approach permits choice based on requirements rather than custom and makes possible

alteration to new unit sizes to satisfy rapid social change. Hence the initial placement of the fixed facilities is a critical decision.

A major determinant of environment is the access to movement from space to space. Those spaces grouped about a room or wide corridor make up a more residential environment through the use of attractive carpets, colors, and materials. Corridors can be more fully utilized; for example, conversation spaces that

do not impede circulation can be provided by window seats and railed landings. Although stairs must conform to fire regulations, their configurations can be a pleasant contribution to the environment.

Structural Spans

The 40-ft span with a 20-ft bay length derived from study of many existing dormitory plans as well as proposed ideal environment spaces. On the national scale, older dormitory types were studied along with the newer ones being built. Whereas 10 years ago most structures were a simple, rectangular shell, a present-day trend seems to involve more complex configurations relating to more complex hierarchies in the social structure.

As a frame of reference, residence halls were classified in five basic plan types:

1. The Double-loaded Corridor—a series of perimeter rooms on both sides of a five-foot + corridor, usually with gang baths and stairs at either end

2. The Gallery Plan—a variation of the Double-loaded Corridor with rooms on one side only of an open or closed corridor

3. The Extended Core Plan—a series of perimeter rooms around four sides of a structure. In the center is a core of service rooms including gang toilets, janitor's closets, elevators, etc. A corridor usually surrounds the core on four sides

4. Vertical House—a series of 4, 6, 8 rooms, suites, etc. A stair serving one or two such configurations of rooms or suites is provided, creating the feeling of an individual house

5. Point Tower Plan—usually but not always high-rise with vertical circulation such as stairs and elevators in a center core along with gang baths and service rooms. The rooms, suites, and arrangements are on the perimeter. Shared baths are often used with suites of 4, 6, 8 persons

Once these five types were defined, all plans were classified accordingly, and a study of their structural requirements was begun. These plans were studied not as actually constructed but rather as they would need to be framed to permit maximum adaptability.

Based on these studies, frequency of occurrence charts showed that very few long spans over 35 ft were used and that a corresponding maximum short span of 20 ft was adequate. Coupling this study with spatial needs and assuming a fixed toilet space, it was concluded that a maximum 35- by 20-ft bay would be required. Provision by a given system of bays larger than 35 by 20 ft will, of course, be acceptable provided the required spans are taken care of.

A variety of bay sizes will be needed in addition to accommodate balconies, overhangs, stairways, and elevators. The precise conditions for these accommodations will be defined in the performance specifications for structure.

RATIOS OF CIRCULATION TO GROSS AREA

Fig. 13

COLLEGE AND UNIVERSITY FACILITIES

Handicapped Students

RESIDENCE HALLS

Sleeping and Study Quarters (Fig. 1)

Space There must be a minimum clear floor space in such areas of 6' [183 cm] by 6' [183 cm] enabling a 360° turn by a wheelchair.

Working Area Space clearance under counter, table, and desk tops to be used by a wheelchair student shall be a minimum of 27½" [69.8 cm] in height and 32" [81.3 cm] in width.

Beds Beds shall have minimum dimensions of 3' [92 cm] by 6' [183 cm] and between 19" [48.3 cm] and 22" [55.9 cm] in mattress height from floor level.

Mirrors Mirrors should be adjustably hung (a minimum of 2'-0" [61.0 cm] in length) so that the bottom is 30" [76.2 cm] above floor level. Where this lower height is not feasible, mirrors of greater height shall be tilted from the top to a degree to sufficiently accommodate individuals described in rational.

Electrical Outlets Electrical outlets shall be mounted no lower than 20" [50.8 cm] above floor level.

Handles and Switches Protruding desk and dresser drawer handles shall be installed. Switches for electrical fixtures and equipment shall be of a toggle or push-button type or equipped with pull-chains of a minimum length of 15" [38 cm].

Closets Where one closet is provided for each occupant, the clothes bar should provide two different heights. Three-quarters of the total length should be at 52" [132 cm] and the remaining quarter at 62" [157.5 cm]. To achieve this, the lower bar, three-quarters of the total length, can be suspended from the higher bar. Wall hooks shall be installed within a height range of 40" [101.6 cm] to 56" [142.2 cm]. Shelves of various height intervals shall be installed on the side-closed wall. The top shelf shall not exceed 45" [114.3 cm] in height. Shelves above the clothes bars shall be provided for long-term storage. (See Fig. 2.)

Windows, Heating, and Air Conditioning Windows shall close and open easily, using hardware latches, cranks, or slides which are within the accessibility height limits of 20" [50.8 cm] to 48" [121.9 cm] above floor level. Heating and air-conditioning controls and thermostats shall be mounted within the same height range.

Power Curtain Traverse Rods Power traverse rods should be installed in rooms occupied by the physically handicapped. All controls should be placed within an accessibility height range of 20" [50.8 cm] to 48" [121.9 cm].

PERFORMING ARTS

Aisles Where possible all new theater construction shall have ramped aisles (no greater

than 1 in 12) with no steps (sight lines should be considered). If this is not possible, accessible and level cross aisles between seating sections shall be provided with minimum width of 7'-6" [228.6 cm]. (See Fig. 3.)

The placement of seating areas for the physically handicapped should not block egress routes used in the case of emergency.

Seating Seating space shall be set aside for those in wheelchairs who must remain in their wheelchairs and cannot transfer to the regular seating. The number of *level* floor spaces of at least 36" [92 cm] in width and 4'-4" [132 cm] in length to be provided shall be as follows:

Capacity of assembly space	Minimum number of seating spaces
0-75	2
75-300	3
over 300	3 + 1 for each add'l. 100

Fig. 1

Fig. 2

LECTURE HALLS

Lecture Seating Lecture halls providing fixed seating and desk facilities shall provide spaces of level floor area of at least 36" [92 cm] in

Fig. 3

Fig. 4

COLLEGE AND UNIVERSITY FACILITIES

Handicapped Students

Fig. 5

width and 4'-4" [132 cm] in length. Desk space provided in this area shall have a knee clearance of at least 32" [81.3 cm] in width and a height of 27½" [69.8 cm]. (See Fig. 4.) The number of desk spaces and accompanying level floor areas shall be provided as follows:

Lecture hall capacity	Minimum number of spaces provided
0-50	2
50-100	3
101-200	4
over 200	4 + 1 for each add'l 100

CAFETERIAS

Food Lines Food lines of cafeterias shall employ tray slides no higher than 34" [86.4 cm] in height and, where a security wall or railing runs the length of the line, the area shall be at least 36"

[92 cm] in width for passage as measured from the outer edge of the tray slide. (See Fig. 5.)

Self-Service Areas Salad bars, condiment areas, beverage dispensers, utensil racks, and other areas where self-service is required shall provide access within the unilateral vertical reach range of 20" [50.8 cm] to 48" [121.9 cm].

Dining Area Tables shall be provided within the dining area which provide a knee clearance of at least 27½" [69.8 cm] in height and 32" [81.3 cm] in width.

Pedestal tables are not recommended because the center post hinders wheelchair footrests.

Aisle widths shall be at least 6'-0" [183 cm] as measured from table edge to table edge (Fig. 6, plan "A"), or 3'-0" [92 cm] from table corner to table corner (Fig. 6, plan "B"), in those areas used by persons in wheelchairs.

The width of main aisles, in areas of normal traffic pedestrian flow, shall be at least 6'-0" [183 cm] to allow two wheelchairs to pass each other (Figs. 7 and 8).

Fig. 6

Fig. 7

Fig. 8

RAMPS

Width A ramp shall be at least 4' [122 cm] in width.

Length The inclined section of a ramp shall not exceed 30' [9.14 m] in length. At both ends of each 30' [9.14 m] (or smaller) section and at each turning point shall be a level area of at least 6' [183 cm] in length and the width of the ramp.

Gradients In modifying existing spaces: If an area to be ramped has a vertical drop of 3" [7.6 cm] or less and is situated either in an open area or at a door with no closing-device pressure, then a gradient of not greater than 1:4 (25%) shall be used.

In Modifying Existing Spaces If an area to be ramped has a vertical drop of 2" [5.1 cm] or less and is situated at a door with a closing-device pressure, then a gradient of not greater than 1:6 (16.66%) shall be used.

In New Construction Any vertical drop over 1/2" [1.27 cm] shall be ramped using a gradient not greater than 1:12 (8.33%) and preferably 1:16 (6.25%) where feasible. (See Fig. 9.)

Fig. 9

I. Column Spacing

A. Stack Areas No one size is perfect for column sizes or column spacing.

Other things being equal, the larger the bay size, the better.

Column spacing—that is, the distance between column centers—is generally more important in concentrated stack areas than in combined stack and reading areas because in the latter suitable adjustments are easier to make.

Clear space between columns—this is not the space between column centers—in a column range should preferably be a multiple of 3 ft (plus an additional 4 in. to provide for irregularities in the column sizes and for the end uprights in the range).

Range spacing and range lengths have a greater effect on book capacity than the distance between columns in a column range. The reduction of space between range centers by 1 in. increases book capacity by approximately 2 percent. The reduction of space used for cross

aisles at right angles to the ranges is also of importance. (See Fig. 10.)

If practicable, columns should be no greater than 14 in. in the direction of a range, and the dimension in the other direction should be kept down to 18 in. If over 14 in. in the direction of the range is necessary, the column might almost as well be 32 in. in that direction. It could then occupy the space of a full stack section and perhaps enclose a heating duct. If a column is wider than the range, it will jut into the stack aisle. Irregular length stack sections are inconvenient, and can often be replaced to advantage by a lectern or consultation table.

Tables 1 and 2 deal with standard layouts in commonly used module sizes.

The following comments may be useful in connection with Tables 1 and 2.

1. Spacing 3 ft 9 in. or less should be used for closed-access storage only, with ranges not more than 30 ft long and not more than 18 in. deep.

2. Spacing 3 ft 9 in. to 4 ft 1 in. can be used to advantage for large, little used, limited-ac-

TABLE 1 Square Modules with the Column Spacing a Multiple of 3 ft (Plus 1 1/2 ft for the Column itself)*

Bay size	Sections between columns, standard 3 ft	Ranges to a bay	Range spacing on centers
19 ft 6 in. by 19 ft 6 in.	6	5	3 ft 10 1/2 in.
	6	4	4 ft 10 1/2 in.
	6	3	6 ft 6 in.
22 ft 6 in. by 22 ft 6 in.	7	6	3 ft 9 in.
	7	5	4 ft 6 in.
	7	4	5 ft 7 1/2 in.
25 ft 6 in. by 25 ft 6 in.	8	7	3 ft 7 1/2 in.
	8	6	4 ft 3 in.
	8	5	5 ft 1 1/2 in.
	8	4	6 ft 4 1/2 in.
28 ft 6 in. by 28 ft 6 in.	9	8	3 ft 6 1/2 in.
	9	7	4 ft 0 1/2 in.
	9	6	4 ft 9 in.
	9	5	5 ft 8 1/2 in.

* Columns should not be wider than the depth of range. 14 by 14 in. up to 14 by 18 in. is suggested.

By KEYES D. METCALF

LIBRARIES, ACADEMIC AND RESEARCH

Formulas and Tables

The figures given here are at best only approximations and may be altered by local conditions; they are not arrived at by exact scientific calculation.

- Six groups are dealt with; those relating to:
 - I. Column spacing
 - II. Ceiling heights and floor size areas
 - III. Reader accommodations
 - IV. Book storage (excluding problems that are affected by column spacing)
 - V. Card catalogs
 - VI. Government standards

Planning Academic and Research Library Buildings, McGraw-Hill Book Company, New York, 1965.

TABLE 2 Square Modules with Column Spacing Multiple of 3 ft*

Bay size	Sections between columns, standard 3 ft	Ranges to a bay	Range spacing on centers
18 ft by 18 ft	5	5	3 ft 7 1/2 in.
	5	4	4 ft 6 in.
	5	3	6 ft
21 ft by 21 ft	6	6	3 ft 6 in.
	6	5	4 ft 2 1/2 in.
	6	4	5 ft 3 in.
24 ft by 24 ft	7	7	3 ft 5 1/2 in.
	7	6	4 ft
	7	5	4 ft 9 1/2 in.
	7	4	6 ft
27 ft by 27 ft	8	8	3 ft 4 1/2 in.
	8	7	3 ft 10 1/2 in.
	8	6	4 ft 6 in.
	8	5	5 ft 4 1/2 in.
	8	4	6 ft 9 in.

* Columns should not be wider than the depth of the range. 18 by 32 in. is suggested.

COLLEGE AND UNIVERSITY FACILITIES

Libraries

cess stacks with ranges up to 30 ft long. Closed-access ranges up to 60 ft long have been used successfully with ranges 18 in. or less deep, 4 ft or 4 ft 1 in. on centers.

3. Spacing 4 ft 2 in. to 4 ft 6 in. can be used for open-access stack, preferably held to 18 in. in depth with the range length based on the amount of use.

4. Spacing 4 ft 6 in. to 5 ft is generous even for heavily used open-access undergraduate stack if ranges are 15 ft long and 4 ft 6 in. on centers, and in some circumstances up to 30 ft if 5 ft on centers.

5. Spacing 5 ft to 5 ft 10 in. is unnecessarily generous for any regular stack shelving and is often adequate for periodical display cases and for heavily used reference collections.

6. Spacing 6 ft or greater is adequate for newspaper shelving and generous for periodical display cases.

Square bays are more flexible than those that form a long rectangle and are generally somewhat cheaper if the ceiling height is limited. But if the latter are used, the number of suitable sizes can be greatly increased. Table 3 shows possibilities with 22 ft 6 in. in one direction and different spacing in the other one.

Similar tables can be prepared for long rec-

tangular bays 18 ft, 19½ ft, 21 ft, 24 ft, 25½ ft, 27 ft, and 28½ ft in one direction.

If section lengths are changed from 3 ft to some other size, such as 3 ft 1 in., 3 ft 2 in., 3 ft 3 in., 3 ft 4 in., 3 ft 5 in., or 3 ft 6 in., or in countries using the metric system to 90, 95, 100, or 105 cm, tables comparable to Tables 1, 2 and 3 above should be prepared with those lengths as a base.

B. Seating Accommodations

Column spacing is of less importance in connection with seating accommodations than with shelving. Tables 4 and 5 show the maximum number of carrels available on one side of standard-size bays and the number of studies available in such bays.

II. Ceiling Heights and Floor Areas

Minimum and maximum ceiling heights and floor areas involve basic functional and aesthetic problems. Suggestions from the functional point of view are proposed as an aid in reaching decisions.

A. Ceiling Heights

Table 6 suggests functional minimums and maximums.

B. Floor Areas Both the number of floors in a library and the area of each floor may be important functionally and aesthetically. Decisions in regard to them may properly be influenced by the site surroundings, the slope of the ground, and the value of the property.

Table 7 makes suggestions, which at best are only approximations, as to the percentage of the gross square footage of a library building which functionally should be on the entrance or central-services level in a typical academic library.

III. Accommodations for Readers

Seating accommodations for readers and the service to readers are the largest space consumers in most libraries. The required areas depend on:

A. The number of accommodations provided

B. The types of accommodations and the percentage of each

TABLE 5 Faculty Studies and Small Multipurpose Rooms

Bay size	Small faculty study*	Small conference room or generous faculty study†
18 ft	3	2
19½ ft	3	2
21 ft	3	2
22½ ft	3	2
24 ft	4	3
25½ ft	4	3
27 ft	4	3

* A room of this size can house a large desk, shelving, a filing case, and permit a door to open in.

† This will provide for conference rooms for four, an adequate small staff office, or a generous faculty study. It should be at least 8 ft in the clear in one direction and have a total area of over 70 sq ft.

Any small room will seem less confining if it has a window, and since window wall space is generally at a premium, a room can well have one of its short sides on the window wall.

C. Dimensions of the working surfaces for each type of accommodation

D. Average square footage required for each type of accommodation

E. Additional space required for service to readers

A. Formulas for Percentage of Students for Whom Seating Accommodations Are Required The formula used should depend on:

1. The quality of the student body and faculty. The higher the quality, the greater the library use.

2. The library facilities provided. The more satisfactory the seating accommodations and the services provided, the greater the use.

3. The quality of the collections. Superior collections increase use.

4. The curriculum. In general, students in the humanities and social sciences use the library more than do those in the pure and applied sciences.

5. The emphasis placed on textbook instruction, which tends to reduce library use.

6. Whether the student body is resident or commuting and, if the former, whether the dormitories provide suitable study facilities. Heaviest library use in most residential institutions is in the evening; in commuting ones, during the daytime hours.

7. Whether the location is rural, suburban, or urban. Large population centers tend to decrease evening use because of other available activities and attractions.

8. Whether the institution is coeducational or for one sex only. Coeducation tends to increase library use, particularly in the evening.

9. The emphasis placed by the faculty on the library and on nontextbook reading.

10. The percentage of graduate students and the fields in which they work.

11. The institution's policy in regard to use by persons other than those connected with it.

12. The departmental library arrangements which may make available other reading facilities and reduce the use of the central library. Table 8 suggests formulas for percentage of students for whom seating is suggested.

B. Suggestions for Types of Seating Accommodations and the Percentage of Each Type

1. For Undergraduates

a. Tables for four or more. Not more than 20 percent. Should be largely restricted

TABLE 3 Long Rectangular Modules, 22 ft 6 in. in One Direction*

Bay size	Ranges to a bay	Range spacing on centers
22 ft 6 in. by 18 ft	4	4 ft 6 in.
22 ft 6 in. by 20 ft	5	4 ft
22 ft 6 in. by 20 ft 10 in.	5	4 ft 2 in.
22 ft 6 in. by 21 ft 8 in.	5	4 ft 4 in.
22 ft 6 in. by 24 ft	6	4 ft
22 ft 6 in. by 25 ft	6	4 ft 2 in.
22 ft 6 in. by 26 ft	6	4 ft 4 in.
22 ft 6 in. by 27 ft	6	4 ft 6 in.

* A bay of this size will give seven sections 3 ft long between 14-in. columns in the direction of the column range. The column sizes suggested in Table 2 are suitable here.

TABLE 4 Carrels*

Bay size	Open†	Double- or triple-staggered‡	Small closed§	Large closed¶
18 ft	4	4	4	3
19½ ft	4	4	4	3
21 ft	5	4	4	4
22½ ft	5	5	5	4
24 ft	6	5	5	4
25½ ft	6	5	5	5
27 ft	6	6	6	5

* A carrel, as used here, is an area in which a reader is cut off from any neighbor who is closer than 3 ft on either side or front and back and one side. The minimum desirable width of an adequate carrel working surface is 2 ft 9 in., which is as useful as 3 ft for each person at a table with two or more persons sitting side by side. Minimum depth suggested is 20 in.

† Distance apart on centers should be not less than 4 ft 3 in., unless the front table leg is set back 4 to 6 in. and armless chairs are used, in which case the distance on centers can be reduced to 4 ft. Any distance over 4 ft 6 in. is unnecessarily generous. A clear space of 27 in. or more between working surface and partition at the rear is recommended. A shelf above the table interferes with overhead lighting and makes a deeper table desirable.

‡ Distance between centers should seldom be less than 4 ft 6 in.; 5 ft is preferred; anything greater is unnecessarily generous. With triple-staggered carrels, the back of the center one should be held down to no more than 10 in. above the tabletop.

§ The distance between centers should be not less than 4 ft 6 in.; and 5 ft is preferred. Watch out for ventilation. A window is psychologically desirable. Closed carrels are not recommended for undergraduates or any student not actually engaged in writing a dissertation. Glass in the door or grills should be provided for supervision.

¶ A room less than 6 ft long at right angles to the desk will permit shelves above the desk or a bookcase behind the occupant but preferably not both. One less than 6 ft parallel to the desk will not permit a 4-ft long desk, and a second chair, and may make it necessary to open the door outward.

COLLEGE AND UNIVERSITY FACILITIES

Libraries

TABLE 6 Clear Ceiling Heights

Area	Suggested minimum*	Suggested functional maximum†
Book stacks‡	7 ft 6 in.	8 ft 6 in.
Stacks with lights at right angle to ranges§	8 ft 4 in.	8 ft 9 in.
Stacks with lights on range tops functioning by ceiling reflection	9 ft 0 in.	9 ft 6 in.
Reading areas under 100 sq ft	7 ft 6 in.	8 ft 6 in.
Individual seating in large areas	8 ft 4 in.	9 ft 6 in.
Large reading rooms over 100 ft long broken by screens or bookcases	9 ft 6 in.	10 ft 6 in.
Auditoriums up to 1,500 sq ft	9 ft 6 in.	10 ft 6 in.
Entrance or main level with over 20,000 sq ft	9 ft 6 in.	10 ft 6 in.
Floor with mezzanine¶	15 ft 6 in.	18 ft 6 in.

* Heights lower than specified have been used successfully on occasion, but ceiling lights should be recessed and good ventilation assured. Financial savings will be comparatively small.

† Greater heights may be useful aesthetically and provide added flexibility by making areas available for a wider range of purposes.

‡ 7 ft 6 in. is the lowest height which permits an adequate protective base and seven shelves 12 in. on centers (standard for academic libraries) with suitable clearance at the top. The top shelf will be 6 ft 4 in. above the floor, the greatest height that can be reached without difficulty by a person 5 ft tall. Space above 7 ft 6 in. is not useful for storage of open-access collections and will be confusing if used for other shelving.

§ This height used with fluorescent tubes, at right angles to the ranges, permits stack ranges to be shifted closer together or farther apart without rewiring, and is high enough so that heat from the tubes will not damage the books on the top shelf. If the fixtures are flush or nearly flush with the ceiling, the clear height can be reduced a few inches.

¶ Mezzanines provide inexpensive square footage if they occupy at least 80 percent of the floor area (building codes may prohibit them unless mezzanine is partitioned off and made a separate unit), and if the overall height of the two resulting levels is not much more than 6 ft greater than would be provided if there were no mezzanine.

to those in reserve-book and reference rooms.

- b. Lounge chairs. Not more than 15 percent. Should in general be restricted to lounge areas, smoking rooms, current-periodical rooms, or used to break up unpleasantly long rows of other types of accommodations. In many libraries 8 to 10 percent of seating of this kind is adequate.

- c. Individual accommodations. Up to 85 percent. These should provide in most cases for working surfaces cut off from immediately adjacent neighbors,

by aisles or partitions on one, two, or three sides. The partitions should be high enough—52 in. for men—so that heads do not bob up or down above them and cause visual distraction. These accommodations may include:

- (1) Tables for one. These can be quite satisfactory along a wall or screen if the readers all face in the same direction.
- (2) Tables for two with partitions down the center. See Fig. 5b. For limited use only.
- (3) Tables for four or more with par-

TABLE 7 Suggested Formulas for Percentage of Gross Square Footage Functionally Desirable on the Central-Services Level*

Gross building area in sq ft	Size of collections in volumes	Minimum percentages of gross area on central-services level
Under 20,000	Under 100,000	40-50
20,000-45,000	100,000-250,000	33½-40
40,000-80,000	250,000-500,000	25-33½
75,000-150,000	500,000-1,000,000	20-30
135,000 +	1,000,000 +	16½-25

* Central services as used here include the main control point, circulation and reference services, reference and bibliographical collections, the public catalog, and acquisition and catalog departments.

These computations are approximations only, but smaller figures than those in the last column will often necessitate shifting part of the central services to other levels and incidentally may add considerably to staff payrolls.

TABLE 8 Formulas for Percentage of Students for Whom Seating Accommodations Are Suggested

Type of institution	Percentage
Superior residential coeducational liberal arts college in rural area or small town	50-80
Superior residential liberal arts college for men or women in rural area or small town	45-50
Superior residential liberal arts college in a small city	40-45
Superior residential university	35-40
Typical residential university	25-30
Typical commuting university	20-25

titions in both directions. See Fig. 3. A great improvement over a table for four without partitions.

- (4) Pinwheel arrangement for four. See Fig. 8c. Satisfactory, but requires more space than (3) above.
- (5) Double carrels with readers facing in different directions. See Fig. 5b. Not as satisfactory as (6) below.
- (6) Double-staggered carrels. See Fig. 7a.
- (7) Pairs of double-staggered carrels on both sides of a screen. See Fig. 7b.
- (8) Triple-staggered carrels in place of three stack ranges or in a large reading area.
- (9) Rows of single carrels at right angles to a wall in book-stack or reading area. See Fig. 1a.
- (10) Single carrels in place of last stack section at the end of a blind stack aisle. See Fig. 1b.
- (11) Typing carrels similar to (10) above, but with special acoustic protection.
- (12) Rows of double carrels in a reading area or in place of two stack ranges. See Fig. 6.

Closed carrels are rarely recommended for undergraduates. Shelves in carrels tend to en-

TABLE 9 Suggested Working Surface Area for Each Person

Type of accommodation	Minimum size	Adequate size
Table for multiple seating	33 in. by 21 in.*	36 in. by 24 in.
Individual table or open carrel for undergraduate	33 in. by 20 in.†	36 in. by 22 in.
Open carrel for graduate student without book shelf over it	36 in. by 24 in.‡	
Carrel, open or closed, for graduate student writing dissertation, with a book shelf	36 in. by 27 in.§	48 in. by 30 in.
Faculty study	48 in. by 30 in.	60 in. by 30 in. if there is shelving over it

* Recommended only for reserve-book use or for a college for women.

† A space of 33 by 20 in. goes farther in an individual accommodation than at a large table because others do not intrude on the space.

‡ Shelves are not recommended over open carrels because they make it easier for an unauthorized student to monopolize one.

§ A shelf over a carrel table requires additional depth because it interferes with lighting. A closed carrel should preferably have a window, glass in the door, and more space around the table than an open one, or claustrophobia may result.

COLLEGE AND UNIVERSITY FACILITIES

Libraries

Fig. 1. Carrels at right angles to a wall. (a) Suggests sizes and spacing and shows elevations. (b) Carrel in place of last stack section next to a wall. The working surface of the carrel should be in line with the stack range instead of the aisle in order to make it easier to get into the chair.

Fig. 2. Carrels with shelves. (a) Shelf in front of reader. The table should be 5 in. deeper than one without a shelf, and adequate spacing between carrels may be difficult to arrange. (b) Shelf at one side instead of in front. (It can be at either side.) This requires more width but less depth. (c) Shelf at one side facing the aisle. This can provide more shelf capacity and greater privacy; it also demands greater total width.

courage undesirable monopolization. A shelf outside the carrel with an open or locked cupboard provides for books and papers to be reserved and makes possible longer hours of carrel use.

2. Graduate Student Accommodations

a. At tables for multiple seating. Not recommended.

b. Open carrels of any of the types proposed in 1 above. Graduate carrels may have shelves over the working surface, but this will require deeper table tops because of lighting problems, unless the shelves are installed at one side. See Figs. 2a, b, and c.

c. Closed carrels. See C and D below for working surface dimensions and square-footage requirements. Closed carrels require special care for satisfactory lighting and ventilation. Unless larger than necessary to provide adequate working surfaces, claustrophobia tends to result. A window for each carrel or an attractive grill on at least one side will help.

3. Faculty Accommodations. If possible, closed studies should be provided for faculty members engaged in research projects which require the use of library materials. Limited assignment periods are suggested. They should not be used as offices. See C and D below for working surface dimensions and square-footage requirements.

C. Dimensions of Working Surface for Each Type of Seating Accommodation Table 9 gives suggested minimum and adequate dimensions.

COLLEGE AND UNIVERSITY FACILITIES

Libraries

D. Average Square Footage Required for Different Types of Accommodation The square-footage requirements suggested in Table 10 are at best approximations, but may be helpful in preliminary stages of planning.

E. Additional Space Required for Service to Readers Space for direct access to seating accommodations is dealt with in Table 10 and elsewhere. Additional space required includes:

Assignable Areas

The public catalog.

Space around the bibliographical and reference and current-periodical collections which is required because of heavy use.

Public areas outside service desks.

Special accommodations for microfilm reproductions, maps, manuscripts, archives, and other collections not shelved in the main stack area. These may include audiovisual areas of various types.

Staff working quarters.

Nonassignable Areas

Entrances, vestibules, and lobbies

Corridors

Areas used primarily as traffic arteries

Stairwells and elevator shafts

Toilets

Walls and columns

It is suggested that not less than 25 sq ft per reader in assignable or nonassignable areas will be required for the services in these groups, and that unless the special accommo-

dations mentioned above are held to a reasonable minimum and careful planning is provided throughout, the 25 may have to be increased to 35 sq ft.

Seating Accommodations As an aid in planning layouts, suggestions are presented for arrangements for seating accommodations in reading areas and book stacks. Remember that academic and research (not public) libraries are under consideration, and the sizes and arrangements suggested are for academic and research use.

1. Single open carrels with the long axis of the tabletops at right angles to a wall. These may be in reading areas, or in book stacks with walls on one side, a subsidiary cross aisle on the other, with the end of stack ranges beyond the aisle, or they may take the place of the last stack section in a range. Single carrels should preferably be fastened to the wall or floor in some way so as not to get out of position. (See Fig. 1a and b.)

2. Single closed carrels along a book-stack wall and opening into a subsidiary stack aisle. These are quite similar to the open carrels described above, but have partitions and a door and, unless considerably larger, they may be difficult to ventilate and to light and tend to cause claustrophobia. Partitions to the ceiling are not recommended for undergraduates, but if the area, including the adjacent aisle, is at least as much as 5 ft by 6 ft 8 in., it can be used for graduate students if there is glass in the door. Light from an outside window will

Fig. 3 Reading-room table with dividing partitions. Not very satisfactory if table seats more than four and reader is hemmed in on both sides. If he leans back, he is too close to his neighbor. If light is hung from the partition, it tends to cause an unpleasant glare. If partitions between readers sitting side by side are extended on both sides to provide more privacy, they become too confining.

Fig. 2 (cont.) Carrels with shelves.

TABLE 10 Approximate Square-footage Requirements for Different Types of Seating Accommodations^a

Type of accommodations	Requirements, sq ft		
	Minimum	Adequate	Generous
Small lounge chair ^b	20	25	30
Large lounge chair ^c	25	30	35
Individual table ^d	25	30	35
Tables for four ^e	22½	25	27½
Tables for more than four ^f	20	22½	25
Individual carrels ^g	20	22½	25
Double carrels ^h	22½	25	27½
Doubled-staggered carrels ⁱ	22½	25	27½
Triple-staggered carrels ^j	22½	25	27½
Double row of carrels with partitions between, placed in a reading room or in place of two stack ranges ^k	22½	25	27½

^a The figures used here include: (1) area of working surface if any; (2) area occupied by chair; (3) area used for direct access to the accommodations; and (4) reasonable share of all the assignable space used for main aisles in the room under consideration.

^b These chairs if in pairs should be separated by a small table to prevent congestion and to hold books not in use.

^c Large lounge chairs are expensive, space-consuming, and an aid to slumber. Rarely recommended.

^d Individual tables are space-consuming, are generally disorderly in appearance because they are easily moved, and result in a restless atmosphere from traffic on all sides. Not recommended except along a wall or screen.

^e Tables for four are the largest ones recommended, unless pressure for additional capacity is great.

^f Tables for more than four are space savers, but few readers like to sit with someone on each side. They will avoid using them as far as possible.

^g Individual carrels are economical in use of space if placed at right angles to a wall, adjacent to an aisle that must be provided under any circumstances. They reduce visual distraction if partitions 52 in. or more in height are provided on at least two of the four sides. See Fig. 5a and d.

^h Double carrels are useful, but the staggered ones described below are preferred.

ⁱ Double-staggered carrels are as economical of space as tables for four and reduce visual distractions. See Fig. 7a.

^j Triple-staggered carrels are as economical of space as tables for six or more and reduce visual distraction.

^k Double rows of carrels are economical in space use and reduce visual distraction. See Fig. 6.

COLLEGE AND UNIVERSITY FACILITIES

Libraries

help. Fig. 4b shows a closed carrel with a door.

3. Single carrels in place of a stack section at the end of a book range. (See Fig. 1b.) As far as space use is concerned, this is the most economical way to provide a seating accommodation, and it gives a great deal of seclusion, which many readers want. It presents four problems, however, as follows:

a. The space from front to back is limited to the distance between range centers, which in some cases is minimal.

b. Unless the table top is specially designed to occupy the full depth of the double-faced range, as shown in Fig. 3, it may be difficult

to get into the chair because the table top will jut out into the aisle.

c. Some readers, particularly if there is no adjacent outside window, will feel too shut in for comfort.

d. Since the seat is at the end of a blind aisle, the length of the range should not be more than half that of a range with cross aisles at both ends.

4. Single seats facing a reading room or stack wall or a high partition down the center of a regular reading room table, sometimes with a high partition at the sides projecting 6 in. beyond the table top into the aisle, to cut one off from his neighbors. There is no place to

look out, except directly at the neighbor to the right or left when leaning back in the chair. They are not recommended, except in an open area in groups of four where the reader can look out in at least one direction, because few students enjoy facing a blank wall, unless they can look out at least a few feet on one side without seeing a neighbor close at hand. (See Fig. 3.) Single carrels in a sawtooth, or what is known as a dog-leg arrangement, shown in Fig. 4c, are preferable to those directly facing a wall, as the reader can look out on one side and still is protected from his neighbors. They require no additional space.

5. Double carrels in rows in a reading room

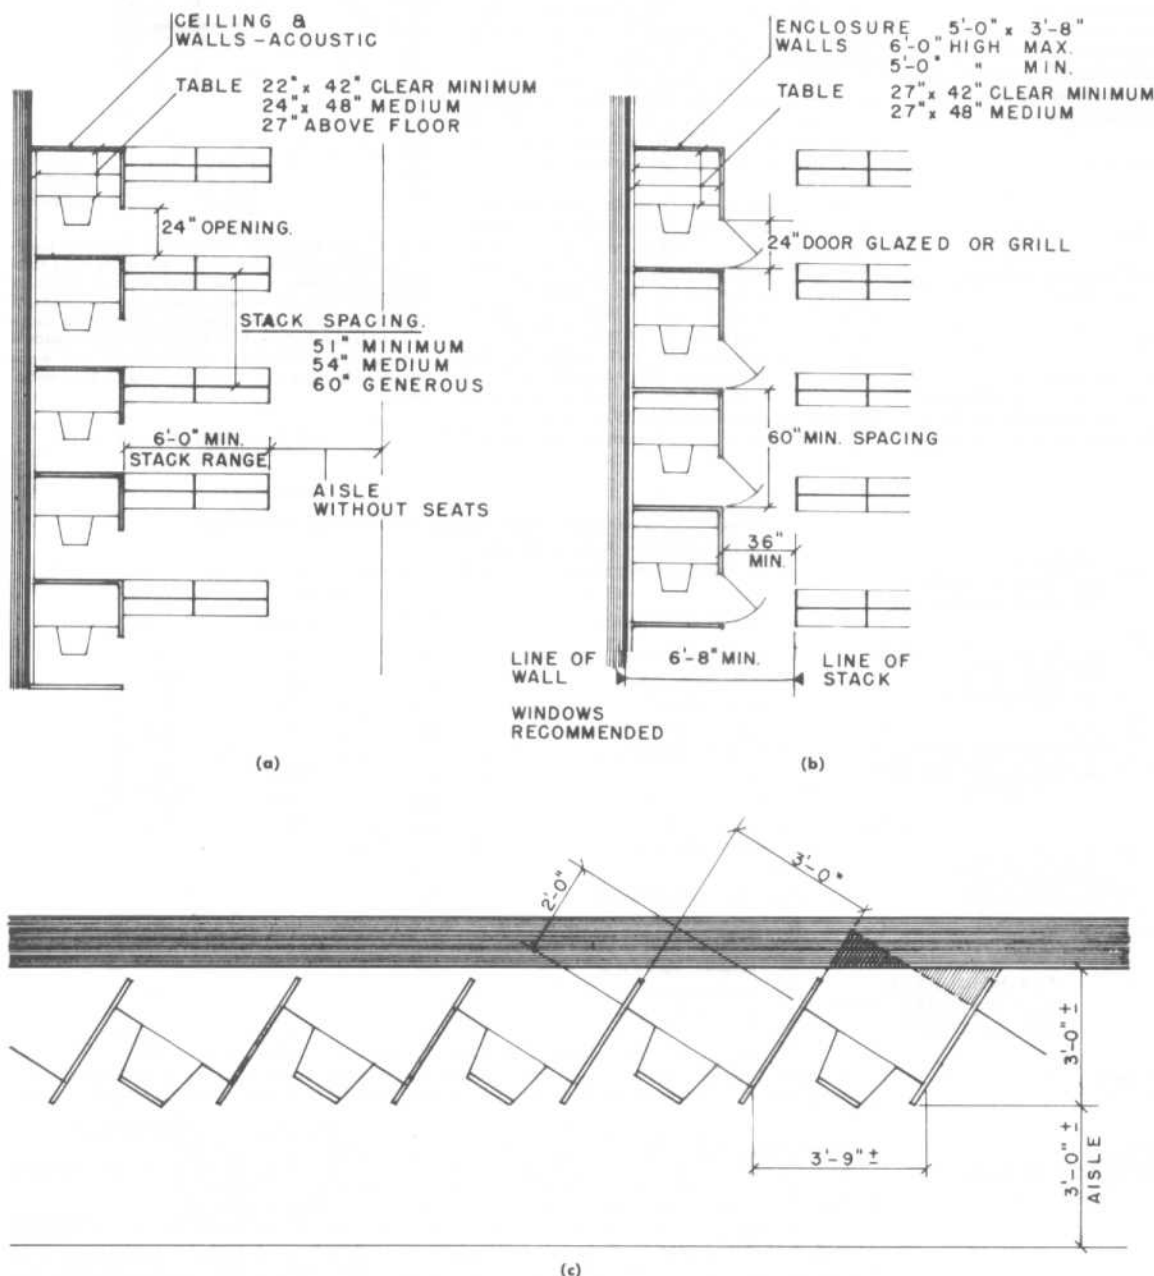

Fig. 4 Other types of single carrels. (a) Partly open typing carrel in place of last stack section with acoustically protected walls and ceiling aided by adjacent books. Absence of other seating close at hand makes doors unnecessary. (b) Closed carrel with door and shelf. If there is no window, wider spacing is desirable to prevent claustrophobia. Ventilation and lighting will present problems. (c) A dog-leg carrel is a compromise for one facing a wall, which is disliked by many, if partitions are extended enough to provide seclusion. The carrel is open on one side.

Fig. 5 Open carrels along a wall or a partition at least 52 in. high. (a) Carrels along a wall all facing the same way. (Recommended.) (b) Carrels along a wall in pairs. (Possible, but they back up to each other unpleasantly.) (c) Carrels facing a wall. (Not recommended. If there are side partitions, reader has "blinders." If he leans back, his neighbor is close at hand.) (d) Carrel elevation to show desirable height of partitions to prevent visual distraction. The left-hand carrel shows a rounded type of construction and the right-hand one a square type.

separated by partitions which are at least 52 in. in height in the front and on one side of the working area. Partitions in front can be held down to no more than 3 to 10 in. above the table top because a full view of one's neighbor all the time is less distracting than a head bobbing up and down occasionally; but 52 in. above the floor is preferable. (Fig. 5d.)

6. Double carrels in rows in place of two stack ranges. A size of 33 by 22 in. can be used in place of two stack ranges when ranges are 4 ft 3 in. on centers. A size of 36 by 22 in. can be used comfortably with ranges 4 ft 6 in. on centers. By placing one or both end pairs at right angles to the others, the carrel range and the stack range length can be made to match with table tops and distances between centers of standard size. (See Fig. 6.)

7. Double-staggered carrels with the adja-

cent table tops overlapping by one-half their depth, placed along walls, with 4 1/2 ft minimum on centers and 5 ft preferred.

8. "Pinwheel" groups of four carrels, preferably in a reading alcove. If the alcove is 12 by 12 ft in the clear, table tops 22 by 36 in. are recommended, with partitions at least 52 in. in height, which extend 6 in. beyond the end of each table. Shelves are ordinarily not recommended for these cases, particularly if the table top is less than 27 in. deep.

This arrangement fits perfectly in a 27-ft column spacing with two alcoves to a bay. If the module size is 25 ft 6 in., the space in each alcove will be reduced a total of 9 in., and one of the shelf sections will be only 27 in. It can be used for shorter shelves or set up as wall space for a bulletin board or for a picture or other decoration.

If ventilation is adequate, alcoves can be partially closed in on the fourth side by a single or double-faced book section, which may help to use space to advantage and make possible the best utilization of the available bay size. The main aisle between double rows of alcoves can be as narrow as 4 1/2 ft. (See Fig. 8b and c.) Pinwheel groups have been successful in large reading areas, but they tend to give an impression of disorderliness when not in an alcove.

9. Carrels in alcoves with tables for four installed with 52-in.-high partitions in each direction. These alcoves may be as little as 9 ft deep and 11 ft 3 in. to 12 ft wide in the clear. With a 25 ft 6 in. bay and 4 ft 6 in. main aisle, an unusually large capacity is possible. (See Fig. 8b and c.) With a 27-ft bay, the space utilization is still good, and the main aisle can be widened to 6 ft.

Libraries

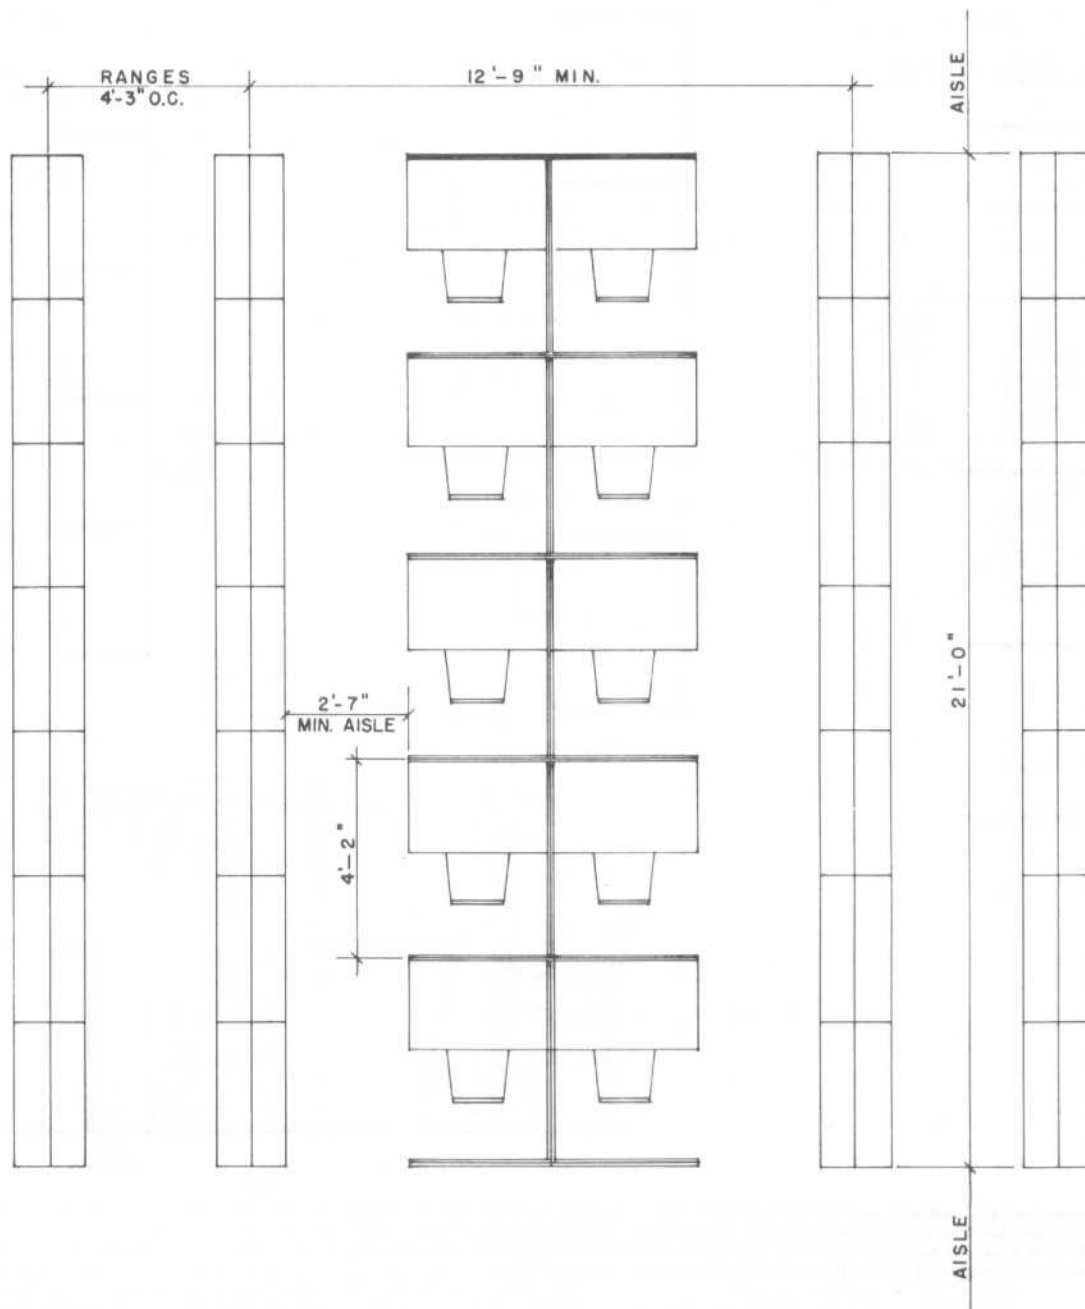

Fig. 6 Double rows of carrels in bookstack or reading area in place of two stack ranges.

IV. Book-Stack Capacity

Book-stack capacity is based on:

- A. The number of volumes shelved in a standard stack section
- B. The square-footage requirements for a standard stack section.

A. The Number of Volumes Shelved in a Standard Stack Section The number of volumes that can be shelved in a standard stack section depends

on: (1) Book heights and the number of shelves per section; (2) book thickness; (3) the decision in regard to what is considered a full section.

1. *Book Heights and Shelves per Section.* Stack sections in academic libraries are considered standard if they are 7 ft 6 in. high and 3 ft wide. Sections of this height make possible seven shelves 12 in. on centers over a 4-in. base. This spacing is adequate for books which are 11 in. tall or less, which, as shown in Table

11, include 90 percent of the books in a typical collection.

It is suggested that most of the remaining 10 percent will be concentrated in a comparatively few subjects, that 70 percent of this 10 percent will be between 11 and 13 in. tall, and that six shelves 14 in. on centers will provide for them.

2. *Book Thickness and the Number of Volumes That Can Be Shelved Satisfactorily on Each Linear Foot of Shelving.* No two libraries

volume; (b) binding policy, particularly for pamphlets and serials and periodicals; (c) the collection under consideration.

A commonly used formula for thickness of books is shown in Table 12.

TABLE 12 Volumes per Linear Foot of Shelf for Books in Different Subjects*

Subject	Volumes per foot of shelf	Volumes per single-faced section
Circulating (nonfiction)	8	168
Fiction	8	168
Economics	8	168

Technical and scientific	6	126
Medical	5	105
Public documents	5	105
Bound periodicals	5	105
Law	4	84

* This table is in common use by stack manufacturers.

3. *The Decision on When a Section Is Full.* In Table 10 a suggested number of volumes per single-faced section is proposed. It is evident that if books are shelved by subject, it is unwise to fill the shelves completely, and any estimate must be an approximation. For many libraries 125 volumes per stack section is considered safe.

B. *Square-footage Requirements for a Standard Stack Section.* The square-footage requirements for a standard stack section depend primarily on: (1) range spacing; (2) range lengths; (3) the number of cross aisles and their widths; (4) cross aisle area charged against adjacent reader accommodations; (5) nonassignable space.

1. *Range Spacing.* Range spacing should be based on column spacing, on shelf depths, which are discussed in a below; and on stack-aisle widths, dealt with in 2 below.

a. *Shelf depths.* Depths as used here are based on double-faced bracket shelving with 2 in. between the back of the shelf on one side of the range and the back of the shelf on the other side. Shelf depths specified by stack manufacturers are 1 in. greater than the actual depth, that is, a 7-in. "actual" shelf is called an 8-in. "nominal" shelf, because 8 in. is available if half the 2 in. noted above is assigned

8 in. or less	90
9 in. or less	94
10 in. or less	97†
Over 10 in.	3

* Adapted from Rider's Compact Book Storage, p. 45.

† An 8-in. actual, i.e., a 9-in. nominal depth shelf, will house a 10-in.-deep book without difficulty, unless there is another deep book immediately behind it. Most books over 10 in. deep will be more than 11 in. tall and should be segregated on special shelving which is more than 9 in. in nominal depth.

represent the average in research and academic libraries), a shelf with 8 in. actual depth, together with the space available between shelves on the two sides of a double-faced section, will provide for practically any book that does not have to be segregated because of its height, and 8-in. actual depth shelves (they are designated by the manufacturers as 9-in. shelves) are recommended in place of the 7- or 9-in. actual-depth shelves which are commonly used. In many libraries a 7-in. actual-depth shelf is suitable for a large part of the collections.

2. Stack-aisle Widths and Stack-range Lengths. Stack-aisle widths should be based on the amount of use by individuals and by trucks and the length of the ranges before a cross aisle is reached. Other things being equal, the longer the range, the wider the aisle should be. Table 14 suggests desirable stack-aisle widths in conjunction with stack-range lengths under different types and amounts of use.

Do not forget that stack-aisle widths must be based, indirectly at least, on the column spacing, and are affected as well by the shelf depths discussed in 1a above, if columns are not to obstruct the aisles. The distance between column centers should be an exact multiple of the distance between the center of parallel stack ranges within the stack bay, which in turn is determined by the sum of the depth of a double-faced range and the width of a stack aisle.

3. Widths for Main and Subsidiary Cross-stack Aisles. Cross-aisle widths should be based on amount of use and are inevitably affected by the column spacing. Column spacing often makes it difficult to provide any cross-aisle widths except 3 ft or a multiple of 3 ft.

Table 15 suggests desirable cross-aisle widths under different types and amounts of use.

4. Cross-aisle Area Charged against Adjacent Reader Accommodations. The effect on square-footage requirements per stack section and volume capacity per net square foot of stack area, resulting from the provision of reader accommodations in the form of stack carrels, is shown in Figs. 10 and 11. These indicate that the assignment of one-half of the adjacent cross-aisle areas to reader space when carrels are on one side of the cross aisles

TABLE 14 Suggested Stack-Aisle Widths and Stack-Range Lengths*

Typical use of stack	Aisle width, in.†		Range lengths‡	
	Min.	Max.	Min.	Max.
Closed-access storage stack	24	30	30	60
Limited-access, little-used stack for over 1,000,000 volumes	26	31	30	42
Heavily used open-access stack for over 1,000,000 volumes	31	36	24	36
Very heavily used open-access stack with less than 1,000,000 volumes	33	40	15	30
Newspaper stack with 18 in. deep shelves	36	45	15	30
Reference and current-periodical room stacks	36	60	12	21
Current-periodical display stacks	42	60	12	21

* These are suggestions only and not to be considered definite recommendations. Circumstances alter cases.

† Stack-aisle widths of 24 in. should be considered an absolute minimum and are rarely justifiable. Anything under 26 in. is difficult with a book truck, even when the use is light. The minimum range lengths suggested.

‡ Stack-range lengths are often determined by available space, rather than by their suitability. The maximum lengths shown in the table should generally be used only with the maximum aisle widths suggested.

TABLE 15 Suggested Cross-Aisle Widths*†

Typical use of stack	Main aisle		Subsidiary cross aisle‡	
	Min.	Max.	Min.	Max.
Closed-access storage	3 ft	4 ft 6 in.	2 ft 6 in.	3 ft 6 in.
Limited-access stack	3 ft	4 ft 6 in.	3 ft	3 ft 6 in.
Heavily used open-access stack	4 ft	5 ft	3 ft	4 ft
Heavily used open-access stack for large collection and ranges 30 ft or more long	4 ft 6 in.	6 ft	3 ft 3 in.	4 ft 6 in.

* These are suggestions only and not to be considered definite recommendations. Circumstances alter cases.

† In determining minimum or maximum widths, keep in mind the length and width of the book trucks used, as well as the amount of use. Minimum width stack aisles should not be accompanied by minimum cross aisles. From the widths shown in the table, up to 4 in. may have to be subtracted to provide for adjacent stack uprights and irregularities in column sizes.

‡ If open carrels adjoin a subsidiary aisle, they will make it seem wider, but traffic will tend to be disturbing to the carrel occupants.

If closed carrels open from a subsidiary aisle, they will make it seem narrower.

TABLE 16 Square Footage Required for One Single-faced Standard Section

Range spacing	Square feet with minimum cross aisles*	Square feet with generous cross aisles†	Square feet with adequate cross aisles combined with carrels‡
5 ft 0 in.	8.25	9.00	8.4375
4 ft 6 in.	7.425	8.10	7.60
4 ft 3 in.	7.0125	7.65	7.225
4 ft 0 in.	6.60	7.20	6.75

* Based on Fig. 10, with a 15-ft blind-aisle range on each side of a 3-ft center aisle.

† Based on two 3-ft side aisles and a 6-ft center aisle separated by 30-ft stack ranges.

‡ Based on 3-ft side aisles between carrels and 30-ft stack ranges, the latter separated by a 4 ft 6 in. center aisle. One-half of the side aisles are charged against the carrels, but even on 5-ft centers the carrels occupy only 22½ sq ft, and square footage for a section is low.

COLLEGE AND UNIVERSITY FACILITIES

Libraries

and book-stack ranges are on the other, may increase rather than decrease book capacity per square foot of net stack area, and in addition provide desirable and economical seating accommodations adjacent to the books. See Table 16.

It is evident that a large number of variables are involved in book-stack capacity. Table 16 is based on the square footage required for a single-faced standard section in stack layouts, with different range spacing, range lengths, and cross-aisle widths, as well as stack carrels.

Table 17 shows stack capacity per square foot of area if 100, 125, 150, or 160 volumes per standard stack section is used in connection with 7, 8 $\frac{1}{2}$, 9, or 10 sq ft occupied by each section.

5. *Nonassignable Space.* Nonassignable space includes, as far as its effect on book capacity is concerned, the floor space occupied by columns, mechanical services, and vertical transportation of all kinds. We mention it here simply to call attention to it. In a carefully designed stack for 25,000 volumes or more on one level, nonassignable space should not amount to more than 10 percent of the gross stack area, and with a larger installation considerably less than that.

V. Card Catalog Capacity

In planning a card-catalog room, estimates quite similar to those used for book-stack capacity must be made. They should include:

A. The capacity for each card catalog unit used

B. The square footage of floor space required to file 1,000 cards comfortably

A. *The Capacity of Each Card Catalog Unit.* The capacity of each card catalog unit depends on:

1. The number of trays it contains
2. The depth of each tray and the number of inches of cards that can be filed in it without undesirable and uneconomical congestion
3. The thickness of the card stock, that is, the number of cards that will occupy 1 in. of filing space

1. *The Number of Trays in a Card Cabinet.* This depends on the number of trays in each direction, that is, vertically and horizontally. Cabinets are made in a great many different sizes, but for large installations 6 trays wide and 10 to 12 high are considered standard, giving 60 or 72 to a unit.

A cabinet with trays 14 or even 16 high is possible, with fairly low bases so that the top one will be within reach. This will give 84 or 96 trays to a unit.

Cabinets 5 trays wide of different heights are also available, but may be more expensive per tray unless purchased in large quantities. They have the advantage of fitting into standard 3-ft-wide stack units.

2. *The Depth of the Trays.* Trays can be purchased in almost any depth, but just over 15, 17, and 19 in. might be considered standard. A tray under 15 in. is uneconomical in floor space used if the catalog is large. Those over 19 in. are so heavy when full as to make their use a doubtful blessing.

3. *The Thickness of Cards and the Number That Will Occupy 1 in. of Filing Space.* Experience indicates that 100 average cards to 1 in. of filing space is a safe figure to use today. Cards tend to thicken somewhat as they get older.

Table 18 shows the capacity for cabinets 6 trays wide with different heights and different tray depths, based on 100 cards to 1 in., with the net available filing space filled to a comfortable working capacity. The term "tray

TABLE 17 Volume Capacity per 1,000 sq ft of Stack Area with Different Number of Square Feet and Different Number of Volumes per Section

Sq ft per section ^a	No. of sections in 1,000 sq ft	Volumes per 1,000 sq ft with different no. of vols. per section ^{b,c}			
		100 ^h	125 ⁱ	150 ^j	160 ^k
10 ^d	100	10,000	12,500	15,000	16,000
9 ^e	111	11,100	13,875	16,650	17,760
8 $\frac{1}{2}$ ^f	120	12,000	15,000	18,000	19,200
7 ^g	143	14,300	17,875	21,450	22,880

^a Examination of Table 16 and Figs. 9 to 11 should help in determining area to allow for a single-faced section. This matter has been covered in IVB.

^b Volumes per section has been covered in detail in IVA.

^c If a period is used instead of a comma in the volume count in the last four columns shown above, it will give the number of volumes per square foot available under different conditions.

^d 10 sq ft per section is the cubook formula proposed by R. W. Henderson.

^e See Table 16 for an example.

^f The author suggests that this is a satisfactory and safe figure to use for a large collection accessible to graduate students and a limited number of undergraduates.

^g Adequate for a very large collection with limited access.

^h 100 volumes per section is the cubook formula.

ⁱ The author suggests that this is a safe figure for comfortable working capacity in an average library. See IVA.

^j The number of 150 volumes per section is too often proposed by architects and librarians. While it is a possible figure, it should be realized that it approaches full capacity and should be used only in cases where additional space is immediately available when capacity is reached. The time to consider what comes next will have passed.

^k The number of 160 volumes per section should not be considered for most academic libraries, unless the collection has an unusually high percentage of abnormally thin volumes and individually bound pamphlets.

depth" refers to the overall depth of the cabinet in which the trays are housed. From it 3 in. should be subtracted to obtain the gross filing space available, and comfortable working capacity can be estimated at between 70 and 75 percent of the gross filing space, with a somewhat larger percentage usable with the longer trays.

The capacities noted above can be increased by at least 10 percent before they become completely unmanageable, but it is strongly recommended that the lower figure be used in estimating comfortable working capacity.

B. *Square Footage of Floor Space Required to File 1,000 Cards Comfortably.* The space requirements depend on:

1. The depth of the trays is a somewhat variable factor, as already noted.
2. The height of the cabinets.

TABLE 18 Card Capacity for Standard Card Cabinets Six Trays Wide*

Trays high	Tray length		
	15 in.†	17 in.‡	19 in.§
10	51,000	60,000	69,000
12	61,200	72,000	82,800
14	71,400	84,000	96,600
16	81,600	96,000	110,400

* Cabinets six trays wide occupy approximately 40 in. in width. Five-tray-wide cabinets occupy approximately 33 $\frac{1}{2}$ in. in width and can be placed in a standard 3-ft-wide stack section. They will probably cost more per tray, but they may fit into the available space to advantage, sometimes combined with the wider units.

† A 15-in. tray is estimated to provide 12 in. of net filing space, which, if filled to 7.1 percent capacity, will house comfortably approximately 850 cards which average 1/100 in. in thickness.

‡ A 17-in. tray is estimated to provide 14 in. of net filing space, which, if filled to 7.2 percent of capacity, will house comfortably approximately 1,000 cards which average 1/100 in. in thickness.

§ A 19-in. tray is estimated to provide 16 in. of net filing space, which, if filled to 7.3 percent of capacity, will house comfortably approximately 1,150 cards which average 1/100 in. in thickness. These trays may be uncomfortably heavy when filled to capacity.

3. The space between cabinets set aside for consultation tables and for those who use the catalog. This should depend on the intensity of use at the time of peak loads. A small catalog with heavy use requires much more square footage for 1,000 cards than does a large one with light use.

4. The space assigned to main and secondary aisles used to approach the cards.

Fig. 9 Stack capacity with different range spacing. No allowance is included here for cross aisles. See Figs. 10 and 11 for their effect. Stack capacities used here are on the basis of 125 volumes to each single-faced section.

5'-0" SPACING	33' x 5' = 165	SQ. FT. FOR 2,500 VOLS = 15.1 + VOLS. PER SQ. FT.
4'-6" "	33' x 4 ¹ / ₂ ' = 148 ¹ / ₂	" " " 2,500 " = 16.8 + " " "

Fig. 11 Stack combined with stack alcoves. Nonstandard bay sizes can sometimes be used to advantage without seriously affecting capacity per square foot.

COLLEGE AND UNIVERSITY FACILITIES

Libraries

Fig. 12 Width of catalog cases. (a) Cases which are five trays wide can be fitted into a standard 3-ft wide book section, an arrangement which is sometimes useful. (b) The right-hand case is a standard six-tray width; both cases are in two parts, each seven trays high for additional capacity. Additional horizontal support provided by thicker cross pieces (not shown) will be required in each part.

Figs. 17 and 18 show different arrangements based primarily on the intensity of use and secondarily on the size of the catalog which result in all the way from 1,000 to 4,000 cards per sq ft of floor space for the whole area.

Every library building program should indicate the number of cards that should be housed and any available information about the amount of use at the time of peak loads.

Card catalogs are generally placed in double-faced rows parallel to each other, at suitable distances apart, so spaced that it is possible to go around either end of each row to reach the next one. As catalogs become larger, it may be desirable and perhaps necessary to fill in one

of the ends, making an alcove closed on three sides. This may add to the capacity of the area by as much as 50 percent, but it must be remembered that, if corners are tight together, there is danger of bruised knuckles when a tray from the row next to the corner is pulled out. A 4- to 6-in. break, preferably covered with a filler, is desirable on each side of the corner. A double row of alcoves with a corridor in between, perhaps 6 ft wide, may give the largest possible capacity in a given area.

Suggested layouts for three libraries, each representing a different situation as far as size and use are concerned, are shown in Figs. 16, 17, and 18.

VI. Government Standards

It is possible and in some cases necessary to base space-assignment figures on standards promulgated by governmental authorities supervising the institutions concerned. These standards can be helpful but, like all formulas and tables, they should be used with caution because, as has been emphasized throughout this section, situations differ and circumstances alter cases. With this word of warning, standards for three different groups are noted:

A. California State Colleges Library Standards Based upon library volumes to be housed, the fol-

(a)

(b)

Fig. 13 Consultation table adjacent to catalog cases. (a) If the table is placed between parallel rows of cases with aisles of suitable width, it will prevent obstruction and not require the trays to be carried uncomfortably long distances. (b) This shows an end and front elevation of a consultation table indicating possible widths, heights, and accessories.

COLLEGE AND UNIVERSITY FACILITIES

Libraries

Fig. 14 Consultation table along a wall at right angles to catalog cases. With this arrangement, cases can be placed closer together but trays must be carried considerably farther, and there will be a tendency to try to consult cards without removing trays. Congestion and damage to cards may result.

Fig. 15 Consultation tables in line with and between catalog cases. Consultation tables arranged in this way save steps but partially obstruct use of adjacent trays.

Fig. 16 Catalog for a small library. With 3-ft-wide aisles at end of each row of standard cases six trays wide and ten high, 720,000 cards can be housed in 480 sq ft, giving 1,500 to a square foot. This is adequate spacing for a library with 300 seats.

Fig. 17 Catalog room for a small university library with 1,000 seats. A larger proportion of the area is required for consultation tables and only 1,000 cards per square foot of floor space is provided.

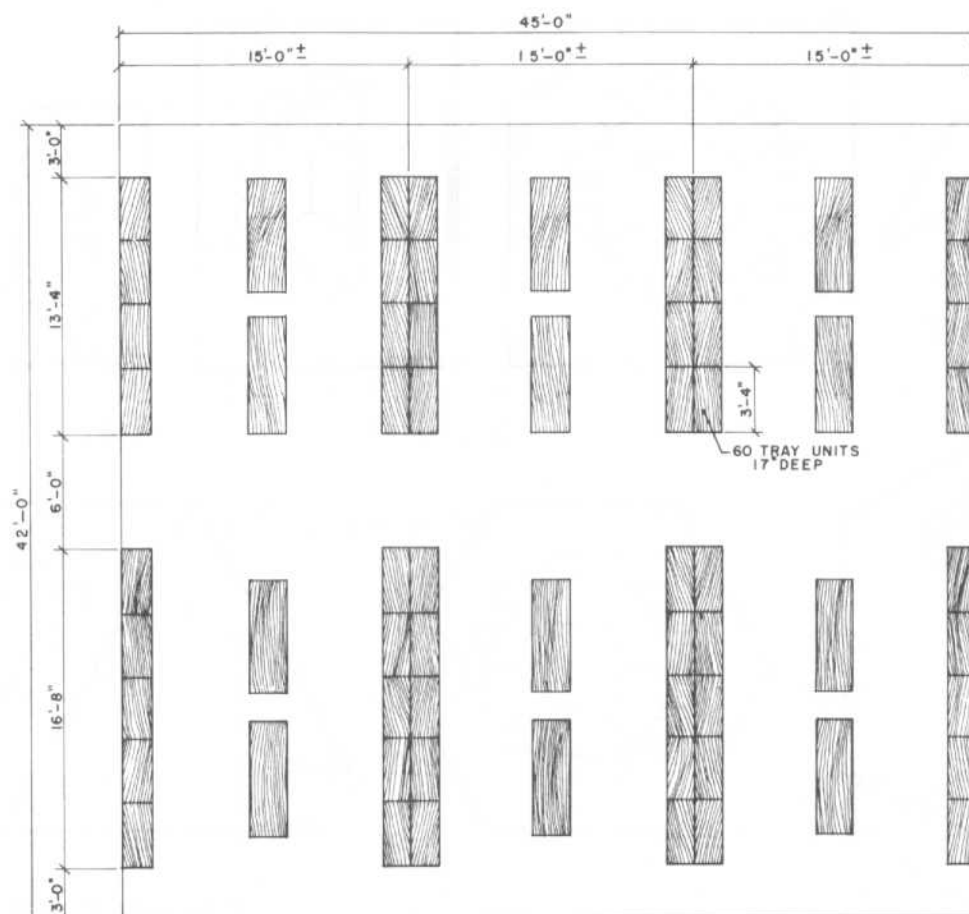

Fig. 18 Catalog room for typical large university library. Provision is made for 1,500 cards per square foot of area with adequate space at tables for readers consulting them.

COLLEGE AND UNIVERSITY FACILITIES

Libraries; Individual Study Carrels

Following space standards are to serve as guidelines for the design of new buildings or additions to existing buildings:

1. Book-stack areas at the rate of 0.10 sq ft per volume.
2. Readers' stations at the rate of 25 sq ft per station, with stations to be provided for 25 percent of predicted FTE (full-time equivalent students).
3. Special materials. An additional area equal to 25 percent of the bound-volume area should be the budget standard for special materials: unbound periodicals, maps, courses of study, and sample textbooks.
4. Special functions:

B. The California State Department of Education in 1955 included this statement in *A Restudy of the Needs of California in Higher Education*.

Libraries.—Total library space requirements, including study halls and all library-staff work areas, were computed on the basis of the following estimates:

1. Reading rooms and study halls, including circulation desks and staff offices: 30 net square feet per station and one station for every four full-time students, or 7.5 net square feet per full-time student.

2. Collections housing the volumes listed below, including work areas, assuming progressively greater use of closed stacks as collections increase in size, and the use of central storage facilities for the larger collections:

First 150,000 volumes	0.10 net sq ft per volume
Second 150,000 volumes	0.09
Next 300,000 volumes	0.08
Next 400,000 volumes	0.07
Second 1,000,000 volumes	0.05

(Note: The total floor area allowed by 1 and 2 above will, it is estimated, provide for the necessary carrels, microfilm and audio-visual facilities, etc.)

3. Size of collection:

State college: 30 volumes per full-time student for the first 5,000 students, plus 20 volumes per full-time student beyond 5,000 students.

University: 100 volumes per full-time student for the first 10,000 students, plus 75 volumes per student for the second 10,000 students, plus 50 volumes per student beyond 20,000 students.

C. The United States Veterans Administration has prepared tables to indicate library space assignments which are based on the number of beds in different types of hospitals. They are hoping by the use of these tables to determine through a computer the square footage to be assigned in a library for each group of space users, library staff, hospital staff, patients, shelving equipment, and so forth.

Student Unions

By CHESTER ARTHUR BERRY, Ed.D.

STUDENT UNIONS

Organization

Since by definition the term college union has two meanings—organization and building—it is necessary to investigate the nature of each. The organization of students, faculty, and alumni which composes the union usually operates with a governing board at its head. This board, which may or may not include representatives of the three groups, is responsible for the operation of the union, although much of the detail is handled by trained staff members and much of the guiding philosophy is originally that of the professional staff. The board itself is concerned largely with questions of policy and implements its policies through the work of various volunteer committees and the paid staff of the union.

The committees consist almost entirely of students and may or may not include members of the governing board. At Michigan State University the following standing committees operate: education, library, merit, outings, publications, publicity, social, and tournament. At the University of Nebraska standing committees for 1950-51 included: general entertainment; special activities; convocations and hospitality; music activities; house and office; public relations; recreation; dance; and budgets, orientation, and evaluation. Regardless of the titles and varying functions, most of the committees serve as the links which connect the boards with the general campus population. The committees plan and execute programs, attending to such details as scheduling, publicizing, decorating, and budgeting. They may choose records for the music library, prints for the art collection. They may help in the orientation of freshmen or study a proposed change in furniture arrangement. They may run the billiards tournament or a book review hour. The committees, sensitive to campus needs and interests, keep the union dynamic, flexible, and busy.

Building

The nature of a college union building varies with each structure, whether approached from either the functional or the physical standpoint. Functionally it is a community center of the first order. It may be a library, art gallery, art workshop, theater, billiard and bowling room, dance center, scene of concerts and forums, informal outing and sports headquarters, office building, hotel, public relations agency, ticket bureau, general campus information bureau, convention headquarters, and post office. The uniqueness of college unions demands custom planning, with the result that, physically, union buildings differ as local situations differ. While the overall purposes of unions remain relatively alike, their functional and structural natures vary.

The functions housed by the union building ideally are those needed to make it the focus

of the recreational, cultural, social, and civic life on the campus. Needless to say, many existing campus facilities such as the library, art museum, gymnasium, or theater cannot and should not be duplicated in a new union building, but the inclusion of as many such facilities as are feasible is desirable to assure that the widest possible range of educational experiences are made available by the union.

Structurally, of course, the union building must house efficiently the facilities required by the union functions while suggesting its purposes by its appearance and design. Its atmosphere should meet the local requirements. If the union is considered "the living room of the campus," it is logical that it reflect the friendliness and warmth of a living room. If it exists largely to serve as a convention center and hotel, it might well offer a more formal environment but, it should be pointed out, such an approach may result in a building and an operation which do not meet the terms of definition of a college union. Whatever the local requirements may be, it seems well to remember that much of the activity of a union is informal in nature and that most of the participation in its activities is carried on by informal college students. The nature of a college union building, then, might well be largely informal to reflect the character of the activities which it houses.

The well-planned union building separates its areas by functions to permit efficient communication, supervision, and operation. It does not place bowling areas next to conference rooms or information desks on upper levels. By separating yet coordinating its components, it continually offers the opportunity for new experiences, so that the walk from the coffee shop to the games area, for example, may lead students past a music room or by an art exhibit. It literally surrounds those who use it with opportunities, and this pervasiveness is a part of the nature of a union.

Facilities and Activities

The diversity of facilities and activities of a union building makes their classification into a few major categories difficult. Nevertheless, there are some aspects of similarity of use, such as noise, service, or supervision, which appear to recommend it. The eight classifications include:

1. Administrative, service, and maintenance
2. Food
3. Quiet
4. Theater
5. Hobby
6. Games
7. Outdoor
8. Miscellaneous

Insistence on rigid separation of activities into areas is, of course, fruitless. Thus, listening to records or working on the college newspaper are hobbies which might well take place in the quiet area, and a bridge tournament held in the main lounge would defy cataloging, involving as it does a quiet hobby which is a game.

Far from definitive, the table merely indicates the type of program which can fit into each area. Much of the duplication of function

which occurs among areas is caused because all facilities are not likely to be found in any union building, with the result, for example, that the ballroom or meeting rooms of a theaterless building may assume many of the functions which are best performed in the theater. Conflicting events also demand alternate expedients, such as showing motion pictures in a large meeting room on dress-rehearsal night or holding a club meeting in a rehearsal room on an evening when meeting rooms are at a premium. The table does not exhaust the flexibility of use by any means. Obviously the small building without cardroom, chess room and ballroom can use its lounges for many of the events listed for those areas. The success and attendance (not necessarily synonymous) of various programs also determine their locations, so that an exceptional music recital might well be held in the theater while a bridge tournament might never require the use of the ballroom.

Not all of the facilities mentioned are discussed here. Some, such as cooperative groceries or ice skating rinks, occur so seldom in connection with unions that they can scarcely be considered as union facilities. Others—bookstore, faculty space, hotel unit, swimming pool, university administrative offices, beauty and barber shops, or chapel—are facilities about which there is widely varying opinion and are usually justified only by local circumstances.

Administrative, Service and Maintenance Areas

A glance at the Classified Facilities Table reveals that union program activities as such are infrequently held in most of these facilities. The program potential of the barber shop and check rooms, for example, is not very high. Closer examination of the table shows that nearly all of the activities are in the nature of services and most of them, in all probability, are performed by paid staff members. If the union board has its offices located away from the administrative offices, the function of staff members is even more pronounced, since many of the services rendered, such as interviewing and training union committee applicants or operating a talent agency or a date bureau, are carried on in the student offices.

Food Areas

Examination of the Classified Facilities Table shows that the variety of food services offered by union buildings equals that of large, modern hotels. They include soda fountains and grill, cafeterias, private dining rooms, service dining rooms, coffee shops, faculty dining rooms, commuters' lunchrooms, women's dining rooms, and banquet rooms.

Since the dining service is the main source of union revenue and caters regularly to a large segment of the campus, it is extremely important that it be planned, constructed, and operated properly.

Functionality As in other union building facilities, the functions of the food service areas vary with the institutions. The existence of

COLLEGE AND UNIVERSITY FACILITIES

Student Unions

other eating facilities on and off the campus, the policies of such facilities (a la carte, five- or seven-day board bills, semester contracts), the location of existing places as well as that of the union building, the prevalence and size of conferences and conventions, and the institution's future plans are some of the items which should be considered.

Food Area Components An all-inclusive union food operation, embracing soda fountain and grills; cafeteria; private, women's, faculty, banquet, and service dining rooms; coffee shops; and commuters' lunchroom includes many components in common with other food operations elsewhere, since the flow process is basically the same. Such components include receiving, storage, meat cutting, vegetable preparation, cooking, bakery, ice cream, salad, service (cafeteria counter or waitress pantry), dining, pot-washing, dishwashing, garbage and trash storage, maintenance, employees' facilities, rest rooms, coat rooms, and offices. All unions neither need nor are able to afford such a comprehensive plant, and only the largest can use all components. Certainly few small unions can afford to hire a butcher for a meat-cutting room, and many provide only refreshment services through a soda fountain or grillroom.

Receiving The receiving facilities of the food area need not be separate from those for the rest of the union building. If combined to serve all the other areas, they may permit the employment of a receiving clerk. A central storeroom for nonperishable items is quite feasible as well, and such arrangement may make it possible for even the smaller unions to use a receiving clerk-storekeeper. Obviously, both vertical and horizontal transportation is needed in such an operation and, since the frequency and perishability of food deliveries are high, the receiving room should be near the food service department.

Storage Storage in the food area includes dry stores or nonperishables, day stores, refrigerated stores, frozen stores, garbage and trash storage. Some may include several subdivisions such as freezers for meat, fruit, vegetables, and ice cream or dairy and meat, fruit, and vegetable refrigerators.

Service Areas The service areas are directly between the various preparation areas and the dining areas in the flow chart. They are usually the places where the food is placed on the individual plates and distributed and may take the form of a cafeteria counter, a serving kitchen or pantry, a waitress station, a serving counter in the kitchen, or a station in a short-order kitchen. In this area food must be kept hot or cold and dishes stored. Dispensing of food occurs here for consumption in the dining area. Refinements and variations of this basic operation differ according to the type of food service being offered.

The prepared food in larger union buildings may go in several directions from the central kitchen. Cafeterias, counters, banquet service kitchens, soda fountains, coffee shops, employees' cafeteria counters, private and public dining room kitchens, and commuter lunchrooms may all be served from this single area, with auxiliary food preparation completed at the serving scene.

Supplying food to these service areas calls for various kinds of transportation. Cafeterias demand a rather steady stream of food for two or more hours at a time, while banquets and private dinners demand that all persons be

Classified Facilities Table

Administrative, Service, and Maintenance:

Offices	Duplicating area
Check and coat rooms	Rest rooms
Information center	Janitorial spaces
Bookstore	Bulletin boards
Non-union offices	Bank
Ticket office	Delivery area
Barber shop	Trash rooms
Beauty shop	Elevator
Post office	Mechanical rooms
Maintenance shop	Storage
Lobby	Employees' lockers and rest rooms
Western Union office	Pay telephones
Shops	Corridors
Lost and found	P-A system

Food:

Soda fountain and grill	Banquet room
Cafeteria	Offices
Private dining rooms	Kitchen
Service dining rooms	Dishwashing room
Coffee shop	Garbage room
Faculty dining room	Refrigeration room
Commuters' lunchroom	Trash room
Women's dining room	

Quiet:

Meeting rooms	Commuters' lockers
Lounges	Box lunch lockers
Music listening room	Commuters' sleeping rooms
Library	International center
Guest rooms	Student activities area
Dormitory	Student organization offices
Chapel	Art room
Other faculty space	

Games:

Table tennis room	Bowling alleys
Cardroom	Chess room
Billiard room	

Hobby:

Photographic studio	Outing club headquarters
Art shop	Amateur radio transmitter
Craft shop	Lending art library

Theater:

Auditorium	Stage house
Stage	Costume shop
Dressing rooms	Costume storage
Shops	Rehearsal room
Lobbies	Ticket office
Projection booth	Offices

Outdoor:

Cement slab	Games
Sun decks	Parking
Picnic areas	

Miscellaneous:

Ballroom	Swimming pool
Music recital room	Ice skating rink
Music practice room	Cooperative grocery
Television room	Ski slide
Convention hall	

Non-Union:

Campus newspaper	Student amateur radio club
College yearbook	Religious advising
Student government	Outing club
Student radio station	Others

COLLEGE AND UNIVERSITY FACILITIES

Student Unions

served nearly simultaneously. Public dining rooms, coffee shops, and soda fountains require more individual service.

Many unions do a brisk take-out business with coffee, sandwiches, and similar refreshment being purchased for consumption outside the building. Much of this business occurs late in the evening when food is taken back to living units for consumption during study hours. The soda-fountain-short-order facilities with their long operating hours and particular menu are best equipped to handle this operation.

Dining Rooms Basically, the function of the dining room is the housing of eaters. If this were its only function, the most economical and efficient way to fulfill it would be achieved by using long tables with stools stored under them and with one large room used for all eating. Since some of the union's education and service programs are carried out in the dining areas, they must do much more than just house eaters. In addition to eating, such activities as card and chess playing, dances, carnivals, entertainment, concerts or recitals, radio forums, or speeches may occur in them. They may house displays or serve as polling places. Meetings and private parties may take place in some of them, classes in etiquette or homemaking in others. In some, conferences or conventions for hundreds may be occurring simultaneously with intimate tête-a-têtes in others. Therefore, more than mere feeding stations, the dining rooms are really gathering places for people. They are important in bringing students, faculty, alumni, staff, and the public together, and they further the unifying concepts of the term union.

The variety of dining facilities found in the larger union buildings attests to the variety of dining functions demanding service. There are the soda fountains or snack bars where a quick bite or cup of coffee may be obtained or where acquaintanceships are made and friendships cemented. This, more than any other single spot on campus, is apt to be the gathering place. Smoke, juke box music, laughter, conversation and crowds typify it, and informality is its keynote. The coffee shops offer informal dining, with or without table service, for a relaxed meal or casual entertaining; the cafeteria provides the low-priced three meals a day; and the dining room, with its linen, service, crystal, and other fine appointments, is the place for a full-course meal, special date, or folks from home. The banquet hall provides for the numerous student, faculty, and other organizational dinners that occur throughout the year but which abound each spring, and the private dining rooms cater to luncheon or dinner meetings for groups, classes, guests, or others.

Quiet Areas

All the quiet areas of the union building need not be connected, but they should be isolated from the noisier sections such as kitchens, workshops, or game areas. Actually, quiet areas subdivide quite easily by function to permit separation. Thus, the living quarters such as guest rooms, guest dormitories, or commuters' sleeping rooms should be separated from the busier lounges and meeting rooms, and their combination permits more efficient operation, supervision, and housekeeping. Student activity areas (rooms with desks and files not permanently assigned) and student offices (permanently assigned spaces) should be together for ease of communication and supervision. The facilities for day students, if they are distinguished from those normally

used by all students, should adjoin each other, including their lunchroom and lounge. The location of meeting rooms near each other permits flexibility of use, easy transfer of furniture and equipment, proper supervision and maintenance resulting from concentration of people, and economy of time between meetings. Lounges may be spread throughout the building to serve various sections and may vary in kind with the sections they serve.

Some of the quiet areas may well be served by separate entrances, included among which could be the chapel, guest quarters, faculty lounge, international center, and student activities and office spaces. Problems of control arise when this situation occurs and it may have some divisive effect on the union, but late operating hours in the newspaper office or guest wing may dictate separation of such areas from the whole building, as may the partial operation of the building during vacation periods.

Music listening (properly soundproofed), library or browsing, and art display rooms can be located together in a sort of cultural center. If this is done, the issuing of records, books, and periodicals and prints from a central location and supervision of that area proves economical. These areas are likely to offer less attraction than the game areas, for example, while supplying experiences of value in broadening the horizons of undergraduates. Their location, however, in a fairly prominent spot may encourage more patronage, but since heavy traffic and accompanying noisiness may result, a choice may be necessary between prominence and peacefulness of position.

Meeting Rooms *Expansibility.* A glance at the Classified Facilities Table shows a wide variety of uses to which meeting rooms and lounges may be put and the degree of interchangeability which exists between the functions of the two areas. If lounges are not to be used for formal programs but solely for spontaneous, informal use, the number of meeting rooms required is larger than that demanded when the use of lounges permits more flexibility. It seems quite certain, at any rate, that the meeting room facility will require expansion early.

The need for many small meeting rooms does not eliminate the demand for larger ones. Enough of each is expensive and the compromise of dividing large rooms into smaller ones by means of folding or sliding walls is a widely accepted one, even though it is a compromise with faults centering largely around the acoustic problem.

Some small meeting rooms, equipped with tables and seating, may double as conference rooms, and the tables themselves may serve as rostrums for meetings as well as conference tables.

The addition of a small 16 mm projection booth at the end of a meeting room simplifies the showing of motion pictures to small groups and eliminates much of the need for transporting and setting up equipment in a room where its noise, light and extension cords detract from the film showing. Such a booth, separated from the meeting room by a wall and glass port, can serve many groups and relieve much of the load normally placed on a theatre, particularly if this booth looks into a larger room which may be subdivided.

Lounges A variety of lounges—men's, women's, faculty, commuters', mixed—may be included in a union building. To a certain extent, the kind of institution involved determines the kinds of lounges which are desirable. A residential college does not need a commuters'

lounge; a women's college probably finds a men's lounge superfluous, although it may wish to have a room available which can be converted to serve such a purpose on special occasions. The existence and location of a faculty club may determine the desirability of a faculty lounge, and the facilities and entertaining regulations in living units bear on the size and number of mixed lounges. The presence and availability of other lounges on campus should be considered in planning the union building lounges.

Reading Rooms While all colleges have libraries, they seem to be considered primarily places for work, so that much can be done by a union browsing or reading room to stimulate good recreational reading habits on the campus. Avoidance of the "library stigma" may be achieved by using comfortable surroundings with air conditioning, fireplaces, decorative plants, proper lighting, by not numbering the binding of books and by meeting the reading needs through a selection committee. Certainly atmosphere is important if the browsing room is to be the sort of place where students and others go for intellectual stimulation or satisfaction, or to while away some time.

The normal functions most likely to be carried out in the browsing room are book, periodical and newspaper storage, reading and book selection. Books are usually shelved around the periphery of the room, and this area should be separated from furnishings and equipment by an aisle wide enough to permit persons to select their books easily. Periodicals and newspapers require less browsing room and may be incorporated in a lounge arrangement of furniture by use of standard racks, or by storage on coffee or other tables.

Music Rooms Marked changes have occurred in the field of music listening. Record changers, the long playing record, tape recorders, and high fidelity have increased tremendously the interest in reproduced music and have offered unions, among others, a real opportunity for improving the level of musical understanding and interest of their students. At the same time, problems of control and usage have been raised since record and tape playing equipment is costly and complex, records easily damaged and the noise potential great enough to transform the so-called quiet areas of the union building into pandemonium. The whole music listening program must be thought out well in advance because this aspect of the union building is dependent to a very great extent upon the manner in which the program functions. Individuals listening to music may do so in booths, small rooms or lounges of varying sizes. They may be using earphones which can disturb no one, commercial combination phonograph-radios, or custom-built high fidelity sets. They may be playing the records themselves or may have requested selections which an attendant is playing from the control point. Records and tapes may be kept with the player and used by anyone, they may be issued by an attendant or they may be private property. Persons using record players may be required to pass a test in the operation of the equipment. Planned group listening such as record coffee hours may be held in a multipurpose lounge equipped with a player or a speaker from a master system, or they may take place in a music lounge specifically designed for music listening, recorded and live. Economy may demand that listening booths be connected with the reading room where group concerts are held. Obviously, many of these items must be

COLLEGE AND UNIVERSITY FACILITIES

Student Unions

considered before the building is planned, because such items as conduits, storage racks, acoustics, equipment, furniture, electrical outlets, glazed doors for supervision, and cataloging methods determine much of the utility of the music room.

Commuters' Areas Nonresident students at colleges near or in metropolitan centers afford many problems to unions, a number of which center around their nonparticipation in most of the union's programs. Their demands on the college naturally differ from those of the residents. They need parking space on the campus, a place to eat a bag or light lunch, storage place for books, lunches, and similar equipment, a spot for resting or, perhaps, an occasional overnight stay. While the union is not necessarily the only location on the campus where such services may be rendered, it seems to be the logical place for many of them. Furthermore, many of the day students are quite likely to eat in the union and to use it as their headquarters, and so it seems logical to plan to meet as many of their demands as possible in advance. If the union building is to be a unifying factor on the campus, it must be prepared to serve the offtimes large[nonresident] segment of the student body.

Guest Rooms Many union buildings contain overnight guest facilities, the extent of which ranges from a single room or suite through large, barracks-like halls to elaborate hotels with full commercial service. The facilities may be intended primarily for university guests, such as convocation speakers, for visiting groups such as athletic teams, for parents or returning alumni, for the guests of students or for conventions. They add to the service aspects of the union building and offer little to its educational program aside from the training the larger units afford to student employees and to students who are majoring in hotel administration. The inclusion of guest rooms in the union building depends upon many diverse elements, such as present and future needs, facilities existing elsewhere, nearby hotels, curricular development, operating hours, operating costs and other union facilities, and careful study is indicated. The fact that the Association of College Unions lists hotel units among the doubtful facilities to be included in union buildings should serve to reinforce the need for careful study.

Student Activities Area A student activities area is a space housing a number of desks and filing cabinets which can be used by varying student organizations for a portion of the academic year. Thus groups which do not need an office or room of their own can be accommodated with a minimum of space allocation. The number of groups and activities on each campus that might use such an area determine its size, and it appears wise to consider that the existence of such an area might well increase requests for its use, thus making a somewhat oversized original plan advisable.

Theater

Need Like so many other parts of the union building, the theater must be custom-built to suit its campus. It is quite likely that a union building located near a modern, well-equipped theater can utilize these facilities for its program and not need a theater of its own. On the other hand, the demands on such a theater by dramatic and other groups may render the theater unavailable for the variety of activities

which the Classified Facilities Table indicates may be held therein, thus making desirable the inclusion of a theater in the union building. With a well-housed drama program already in operation, the theater requirements may be pared down so that nothing more than an auditorium and platform suits the union's needs. Such a solution appears most questionable, however, since it provides little more than a forum for speakers, a location for motion pictures and stage for formal music concerts. Such activities as variety or vaudeville shows, fashion shows, orchestral and choral concerts, sing contests and dance recitals become difficult to present without proper stage, scenery, dressing, shops, wing and lighting facilities. The use of road shows—ballet, drama, opera, and the like—by the union is obviated. It may be that such activities can be housed elsewhere, but the demands on theaters of dramatic groups for practice and for rehearsal and staging time, of music groups for practice and concert time, of assemblies, meetings and conferences for auditorium time, of departments and organizations for space for motion pictures, lectures and demonstrations, indicate that a close study of all present demands upon theater facilities be studied and that future possibilities, particularly as suggested by other campuses with adequate union theaters, be considered before plans are drawn up. The place of other existing theaters and assembly halls in the campus scheme of things, including policies governing their use, should be given grave consideration.

A union theater would seem to suit most of its purposes if it houses the requirements of a fairly orthodox collegiate drama program and adds such items as an elevating forestage-orchestra pit; audience access to stage for variety shows, sing contests and the like; fluctuating seating capacity by means of sliding panels or draperies; reception or lobby lounge; broadcasting facilities; possible combination craft-scenery shops, and still and motion-picture equipment to achieve the flexibility which is an earmark of the union building.

To function completely, the union theater would be composed of:

Auditorium	Projection booth
Stage	Sound system
Forestage	Screen
Orchestra pit	Stage house
Proscenium arch	Lobby
Dressing rooms	Ticket office
Scene shop	Scenery storeroom
Costume shop	Control board
Light booth	Rest rooms
Makeup room	Coat room
Rehearsal room	Lounge or green room

Some of these facilities, such as lounge, coat room, rest room or rehearsal room, may be a part of the union building and serve a double purpose, so that a nearby lounge may be used for receptions or a properly shaped meeting room double for use during live rehearsals.

Arts and Crafts Shops

The variety of offerings which the union's shops can provide is large. Some of these offerings, such as photography, demand specialized facilities and equipment; others, such as leatherwork or jewelry making, require little and can be accommodated in a general shop area. The tools of some crafts may be used in common by participants in other union activities, so that the scene, maintenance, and wood-working shops may use the same power tools

and central materials sources and the camera club and campus publications the same studios. The size of the union and the university, the organizational scheme and expected use of the various shops would determine the possibility of such a combination. Among the arts and crafts activities which a union might embrace are:

Painting	General woodworking
Sketching	Picture framing
Block printing	Cabinet making
Poster making	Metal and jewelry work
Silk screening	Ceramics
Clay modeling	Drafting
Weaving	Photography
Rug making	Leatherwork
Drawing	Graphic arts
Fly tying	Sewing
Plastic work	Knitting

While adherents of nearly each art or craft could develop a list of reasons why their favorite activity should be allocated separate space and equipment, much of it with special requirements such as north light for sketching or humidity control for clay modeling, enough compromises and combinations can be effected to provide a variety of activities within a reasonable area.

Outdoor Games

The extent to which the games area should be developed is dependent in large degree on what is available elsewhere on the campus. The number of games within the union's province which can be played outside might include badminton, bowling on the green, bocce, croquet, curling, clock golf, horseshoes, shuffleboard, table tennis, giant checkers, deck tennis, roque, quoits, and a variety of table games such as chess, checkers, or cards.

Integration of Areas

Some union facilities must be located on the street level; others operate most efficiently on other levels. There are strong reasons for placing food services, information center, bookstore, ticket offices, ballroom, and administrative offices on the ground floor, while other areas such as publication offices or student activity offices may be in less accessible locations. Guest rooms, which receive relatively little traffic and function better in quiet, fit nicely into higher floors and more remote wings. The task of putting the various elements of a union building together so that each fulfills its own function while complementing that of the others is nearly certain to demand compromises. Realism may dictate that such revenue-producing facilities as a bookstore or soda fountain take precedence in location over a music room or browsing library, even though it may be educationally desirable to expose, at least by proximity, those entering the building to the latter rather than the former. Traffic to the most popular areas of the union building should not be so directed that it causes great crowds of people to throng its passages and stairways to the disturbance of other sections and to the detriment of building maintenance. Some seldom-used facilities, such as a ballroom or hobby shop, may finally be placed on the top floor because there is no room elsewhere for them.

Segregation by Function Whenever practical, areas should be separated by function, as previously described in the section on game rooms, where supervision, instruction, and equipment control for all were made possible. Such areas

COLLEGE AND UNIVERSITY FACILITIES

Student Unions

may assist others in their functions when properly located and so, while complete in themselves, they can nevertheless help and be helped by others. Thus, a self-contained game area receives players from a nearby coffee shop, and the presence of such a shop induces gamesters to stop for refreshments when leaving. It is to be hoped that persons walking by a corridor case containing a craft display might be interested in utilizing the out-of-the-way hobby shop.

Some principles in combining the elements of the union building into an entity are elementary. The games area is noisy and should not be next to sleeping rooms or private dining or meeting rooms. Kitchens demand considerable delivery, removal, and storage, hence they should be near driveways, storerooms, and receiving spaces. The information center should be near the main entrance. The theater should have its own exits and entrance and is probably best situated in its own wing. Similar or related activities may suggest combinations such as the ballroom-banquet room or theatre-radio station. The browsing, music, and art

rooms can be worked into a unit which is serviced and supervised by one central control or which, at least during rest periods or emergencies, can be satisfactorily administered by one person.

The kitchen should connect with the ballroom and with certain of the lounges and meeting rooms, even if only by conveyors or elevators, to provide adequate service for receptions, coffee hours, intermission refreshments, and, possibly, banquets. Thus, those areas served by the kitchen but not on the same level must be vertically aligned with it if they are to be serviced by a dumbwaiter.

Public Spaces So far, then, the food areas are best located largely on the ground level with the games rooms not too remote from the refreshment area and with some meeting rooms and lounges directly above the kitchen. The theater crowds at intermission may use the refreshment service if it is not too far distant, hence this wing, which offers some meeting space while sometimes needing additional reception and rehearsal room, might well ad-

join the foot-meeting-room section. A review of this portion of the building so far reveals it to be a busy place with many persons using it for eating, meeting, and theater work. Service facilities such as coat rooms, toilets, and public telephones are needed, and multipurpose lounges prove valuable. If the costume and stage shops are to have any connections with the hobby shops, the latter must be included in this section of the building. By the same token, if the darkroom facilities are to be used by the campus publications, these offices might well be located here.

Reception Center The main entrance, lobby, and information desk go together. In some union buildings the information center includes ticket, cigarette, and other sales, a lost and found service, and, possibly, some office functions.

Figures 1-21 are reprinted from *Planning College Union Facilities for Multiple-use*, Association of College Unions—International, Madison, Wisconsin, 1966.

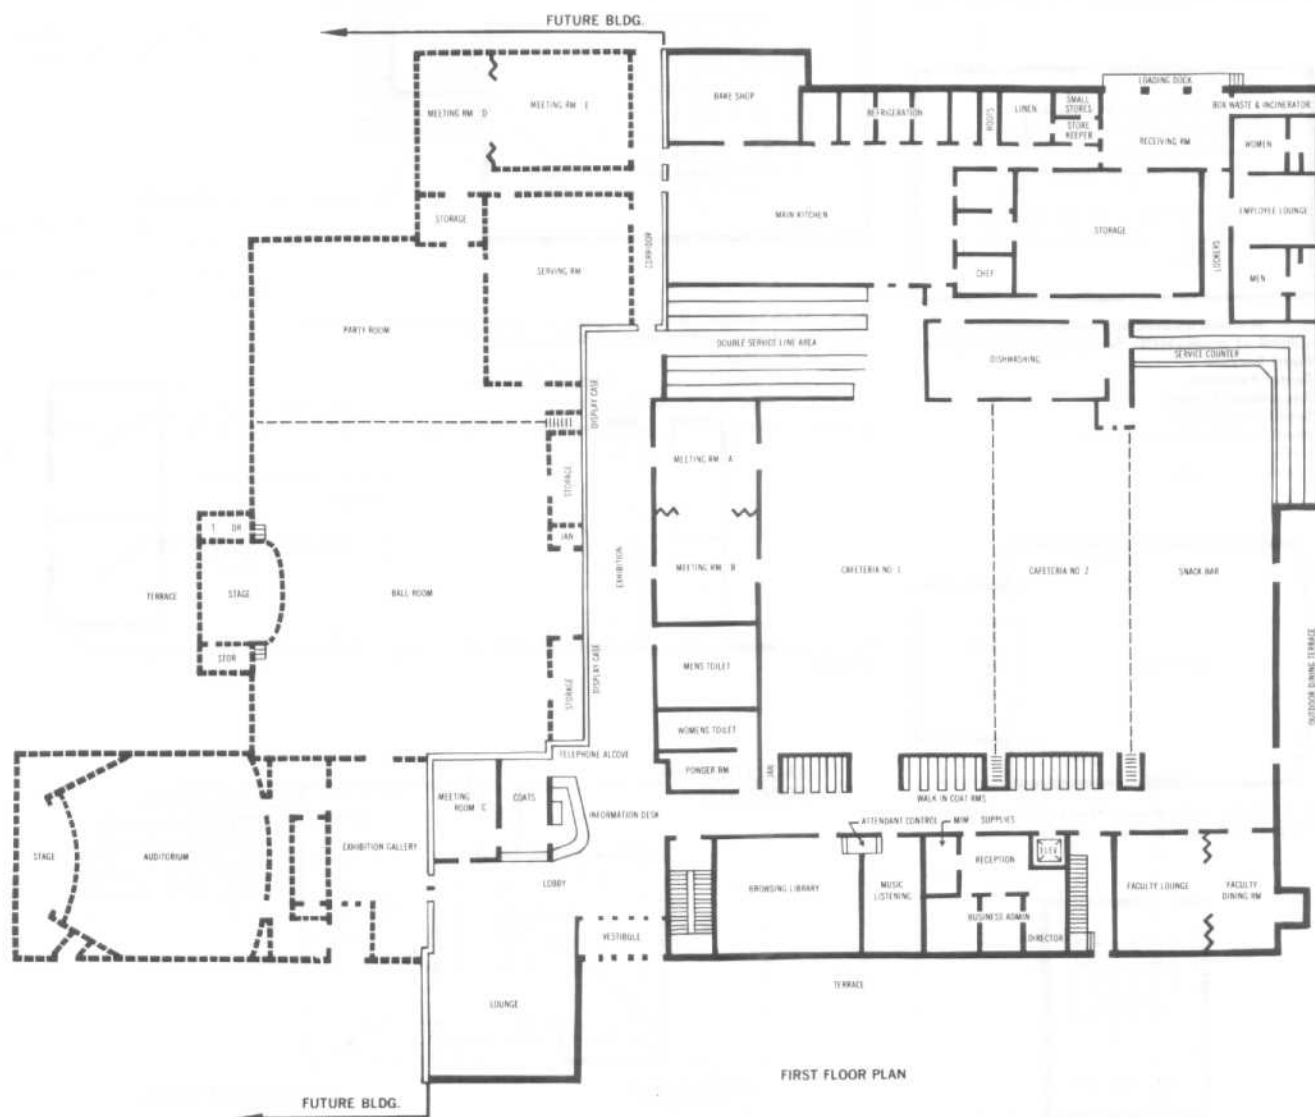

Fig. 1 The core of union facilities at the University of Delaware—solid lines. And the planned future extensions, showing circulation and integration of all units (including how food would be delivered to the future ballroom and private dining rooms)—dashed lines.

COLLEGE AND UNIVERSITY FACILITIES

Student Unions

Smaller unions combine this center with an administrative office and even make it the issuing and supervising center for the music and browsing rooms. Many unions may wish to place a large lounge for receptions next to the main entrance. Coat rooms should adjoin this area, and toilets should be near by.

Administrative Spaces If the advantages of adjoining offices outweigh those of decentralized offices, an administrative suite can be planned wherein equipment and personnel can be used with flexibility. Some office space is needed in the various departments but can be reduced if centralization is adopted. Should decentralized offices be used, the social director might well be housed in the student activities section where the various student government organizations, union committees, and publications hold forth. In this way communication among the various groups and with the social director is improved and a relatively quiet group of activities kept together. If decentralization of offices is adopted, other offices besides the social director's can serve double duty. The business office near the food or bookstore area can offer closer supervision and emergency as-

sistance. A maintenance superintendent's office near the maintenance shop or a reservation office near the information center can provide bonuses in the form of added service.

Quiet Areas The quiet areas, logically enough, occur away from the noisier, highly trafficked ones. Offices; conference and meeting rooms; art, music, and browsing rooms; and lounges go well together, but they cannot entirely be separated from the noisier sections. Meeting rooms with their periodic traffic introduce some noise to an otherwise quiet facility, particularly when larger rooms are in use, and it may be that larger meeting rooms and lounges fit into the noisier section, which includes the food services, while smaller meeting rooms and lounges and conference rooms are combined in a quiet section which embraces of-

fices and other less noisy facilities. While outside noise can interfere with the music room, the considerable amount of sound which originates therein makes the music room a most unlikely component of a quiet area unless it is well soundproofed.

By and large, the quiet areas of the building present most of the demands for late or vacation-time operation. Guest rooms and administrative and publications offices are quite likely to function late at night or during the Christmas or summer vacations, and locating these together with separate access permits their use after the union's normal operating hours. With this in mind it may seem advisable to place the campus radio station alongside the various student offices. Separate use of other areas of the building should also be considered in laying out the floor plans.

COMPUTATION CENTERS

Most experts in the field agree that a computation center for a college or university should be an all-campus facility, administratively under the control either of the Graduate School or of an all-campus committee, rather than an adjunct of an academic department such as mathematics, statistics, or electrical engineering. A currently emerging pattern is the formation of a separate department of computer science with some teaching duties; it usually has some affiliation with the department of mathematics and is possibly not fully responsible for the service activities of the computation center.

Location of a Computation Center, Public Access, and Parking

In choosing a central or peripheral location for a computer, the rapid development of computer use by medical schools, business schools, and behavioral science groups, as well as by physical scientists and engineers, should be considered. Proximity to users must be weighed against the almost certain needs for expansion in the near future. New means are being developed whereby a fast central computer can service simultaneously a number of different input-output stations that may be placed strategically at several points on a campus.

A computation center is visited daily by large numbers of people who come either as clients to have problems done on the com-

puter or as visitors to see the facilities. Hence it is important that adequate parking be provided near the computation center to accommodate both its own staff and these visitors.

Access to the computer facilities must also be provided for the computing machinery and for the supplies that will be needed in its operation.

The functions of a computation center may be different at different institutions, and must be considered in planning its location and space requirements.

A small center with more limited objectives may require a relatively small amount of space at first. However, experience has often indicated that after a small computer has introduced research workers in many areas on the campus to the potentialities of computer use, a larger center is not only desired but justified. Wise planning must take this into account.

Furthermore, experience both on university campuses and in industrial organizations suggests that a single computer of great capability is preferable to a collection of several much slower machines, since both the machine cost and programming cost per unit of computing are cheaper on the single large machine than on several minor machines. It is assumed that the large machine is satisfactory to all parties concerned, is capable of handling the combined workload, and is not idle much of the time. The tenfold increase in cost required for a fast machine may possibly provide a hundred-fold increase in capability, thereby reducing the cost per unit of computing by a factor of ten. This is a real saving if the fast machine is used to capacity, but not if it is used only 10 percent of the time.

Perhaps even more serious than the direct dollar cost is the fragmentation of knowledge that takes place when each small computer has its own staff, communicating poorly, if at all, with similar groups on the same campus. Despite this, groups frustrated by inconvenient or inadequate access press strongly and sometimes successfully for their own installation. A separate problem here is the need for analogue or digital equipment tied directly (i.e. "on line") to a real time experiment, such as a reactor, jet engine test stand, or a human being under some form of medical observation or treatment. Techniques for interrupting large-scale problems for brief uses of the computer are under very active development, but it is difficult at this time to predict whether additional machines of about the present size will be installed or whether even larger machines will be shared by many users, perhaps with the aid of off-site input and output devices.

Public Viewing and Briefing

The main computer room itself is an important showplace. Good public relations require that it be located where visitors can easily see it from a corridor or viewing room through a glass wall. Otherwise, there will be crowding that interferes with the work. A classroom, briefing room, or auditorium, equipped with adequate chalkboard in front, should be placed near the viewing area. This room can be used both for briefing groups who may come to see the computer and for regular instruction in computer science, either in short courses, institutes, or regular university courses.

COLLEGE AND UNIVERSITY FACILITIES

Computation Centers

Computer Space

The main computer room is the heart of a computing center. It must be accessible to the computer staff who operate the machines and to the maintenance engineers who repair the machines and keep them in running order, as well as being strategically located for public viewing (Figs. 1 and 2). It must also be accessible to appropriate storage spaces and to the power supply. Efficient operation requires that the individual machine units in the main computing room be so placed that they are easily accessible for quick repair in emergency, as well as being conveniently located for the operators and the public. If the distance from the back of the computer units to the walls were made 18 in. greater than the distance needed to open the cabinet doors and carry out repairs, this wall space could be used for storage that would be accessible except during maintenance. (However, fire regulations demand that only the absolute minimum of records required for efficient operation shall be kept in the computer room itself.) An upper limit to the distances between computer units may be set in some installations by the available lengths of information cable.

The machines in the main computer room need proper support, cable connections, and air conditioning. In the main machine rooms for most of the larger computers, the underlying fixed floor is built about 18 in. lower than the floors in adjacent preparation rooms or corridors, and it is covered by a strong elevated floor beneath which cable connections can be installed without obstructing the passageways (Fig. 3). The panels may be covered with carpeting or other types of flooring materials, but it is important that the floor be kept free from dust, lint, and static electricity.

In buildings without a recessed subfloor, such as those remodeled for computer use, ramps should be used to connect the elevated

floor with floor areas at a different level in order to permit carts with tape or punch cards, or other equipment, to be rolled in.

Auxiliary card-punch machines, tape preparation units, and printers may be included within the vapor seal enclosing the main computer units, but they should probably be separated from the main room by glass panels to reduce the noise level and dirt. Acoustic treatment of the ceilings is important for noise reduction. Adequate and well-diffused lighting should also be installed in the ceilings of the computer areas.

Some information storage media, such as punched Hollerith cards, punched tape, or magnetic tape, are needed for current use and should be readily accessible; a fireproof storage closet for such items should be adjacent to the computer room. Magnetic tapes are commonly stored in flat, cylindrical cans, placed on racks so that their circular bases are in a vertical plane. Metal file cabinets with drawers designed for standard punched cards are also commercially available.

Maintenance and Mechanical Areas, Power, and Air Conditioning

Adequate space should be provided near the main equipment room for the use of maintenance engineers, whether they be local personnel or representatives of the equipment manufacturer on contract to repair the machines. Undue economy in the space available to maintenance engineers may be no economy at all in the long run, since time wasted in repairing a fast computer may be worth several dollars a minute.

Spaces for auxiliary mechanical equipment for the computer, including the power supply and air conditioning, must be provided close to the main computer room. There are some advantages in having this area adjacent to the working areas for maintenance personnel.

Preparation Areas

For programming there should be a preparation room, or "ready room," near the auxiliary machine room, where programmers may put their programs on tape or cards that the computer can read, and where they may check their programs for errors. A ready room should be equipped with work tables and desk calculators in addition to the auxiliary punch units that may be needed for preparing programs to be read by the computer.

For efficient operation, many people who do not have permanent offices in the computer area need temporary work space there.

A reception desk or counter may be provided in or near the ready room to accept and check in programs to be run on the machine, record completed work, and return it to an appropriate cubbyhole in a large rack, where it may be picked up by the person who submitted it.

Offices, Conference Rooms, Library, and Lounge

Spaces required by the computer personnel, in addition to the preparation areas just described, include offices, conference rooms, library, and lounge or refreshment corner. Conference rooms are needed in which several persons, including the proposer of the problem, may get together to discuss possible methods of attack for its solution. Private offices are needed where people working on problems can concentrate without interruption on the complicated series of steps necessary to program a problem.

A reference library should be readily available to computer personnel. This library should include not only a collection or "library" of subroutines and other programs that may be stored on tape or punched cards but also at least a minimal collection of technical books and journals relating to computing and numerical

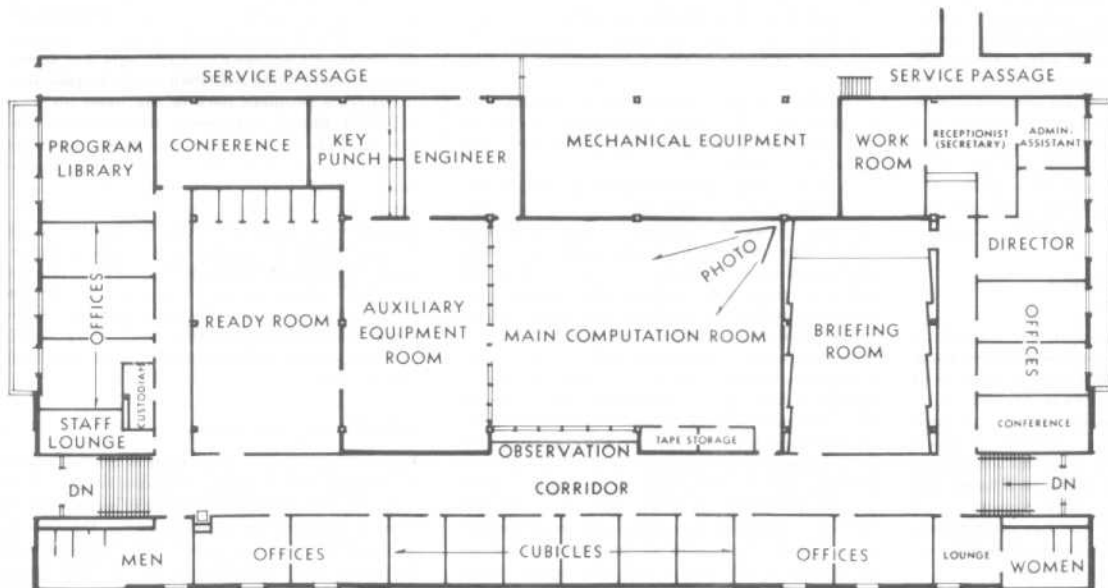

Fig. 1 Plan of computation center, University of Texas.

Regular staff members of a computer center should not only have individual offices where they can work without distraction but also a staff lounge where they can get together to exchange ideas and charge their mental batteries. At the University of Texas Computation Center (Fig. 1), ten offices of 180 square ft each and six cubicles of 100 sq ft each are provided for the use of staff and graduate students, and there is a small lounge in which

A computer installation uses large quantities of materials, such as punch cards, paper tapes,

To prevent damage to the computer by fire or water hazards arising outside the computer room itself, the equipment should be housed in a fire-resistive building and should be protected by fire doors from the rest of the building; the flooring should be of noncombustible construction, and the roof or floor above the computer room should be a watertight slab to which the walls are sealed. Waterproofed walls and proper drainage may be needed to prevent water damage in a basement installation. Local fire protection for certain key computer units may be provided by approved automatic carbon dioxide fire extinguishers rather than by water sprinklers.

COLLEGE AND UNIVERSITY FACILITIES

Computation Centers; Communications Centers

Fig. 3 Elevated floor for a computation center.

Cards, disks, and drums should be kept in waterproof, noncombustible metal cabinets with controlled temperature and humidity if required. Those not in current use should be stored in a separate room close to the computer room. Magnetic tape itself is highly flammable. Duplicate copies of programs and records might be stored in a remote place as insurance against their total loss by a fire in the computer center. Adequate controls should prevent the ducts of the computer air-conditioning system from circulating smoke and fire in case of emergency; it is best to have the computer air ducts independent of the other air ducts in the building. All office furniture in the computer room should be metal.

Hazards other than fire and water that may need to be considered in planning and maintaining a computer installation are those from radiation, magnetic fields, static electricity, dust, insects, or rodents. To protect stored rolls of magnetic tape from loss of information due to local magnetic disturbances, it is best to place their containers on edge in a magnetically protected storage place. To minimize the effects of dust and static electricity, carpets and drapes should be made of materials free from lint and static; the use of dustcloths or dry mops for cleaning should be avoided.

If the incoming power supply for the computer is subject to occasional interruptions, a secondary source of power may be needed to provide continuity of operations. Failure of the air-conditioning system may also cause the computer to shut down within a short time, so there should be a warning alarm that will immediately call attention to such a failure.

COMMUNICATIONS CENTERS

A new building type resulting from new thinking and practice is the communications center. The emphasis of this type of facility is on large-group instruction and on the media to support it. For this reason, it is becoming a college building, centrally located on the campus to accommodate many hundreds of students in large groups throughout the day. It may also be part of an educational park with its facilities available to all school groups in the area. (See Fig. 1.)

The philosophy behind the communications center is a simple one. If the institution feels that large-group instruction fits its needs for economical but effective instruction (as many colleges do believe), it makes sense to put these expensive "supporting" functions together. The communications center can economically provide:

- Shared projection areas, allowing expensive equipment to be kept together in one room. This not only ensures better care of the equipment, but through consolidation, utilization rates can go up.

- Special and expensive lighting and mechanical systems. It is cheaper and less cumbersome, for instance, to air-condition one whole building rather than little pieces of many buildings.

Educational Facilities with New Media, Department of Audiovisual Instruction, National Education Association in collaboration with the Center for Architectural Research, Rensselaer Polytechnic Institute.

- Special and expensive electrical installations.

- Accommodation for weird room shapes; placing one pie-shaped lecture room in many separate buildings creates waste space and odd configurations. Putting many such rooms together in one building allows the good designer to cut down if not eliminate these wasted spaces. (See Fig. 2.)

- Centralization of production facilities. Since many of the items produced will be used in the large-group lectures, it makes sense to consolidate all production and "support" activities in the building (Fig. 2).

- A central "focal" point for faculty training in effectively using presentation and other instructional media.

The communications center does not become the property of any one discipline or department on campus; its use will be encouraged for all departments needing it. It will occupy a focal point on the campus, probably at the crossroads of major circulation paths.

The types of facilities the communications center may include cover those in many areas. (See Fig. 3.)

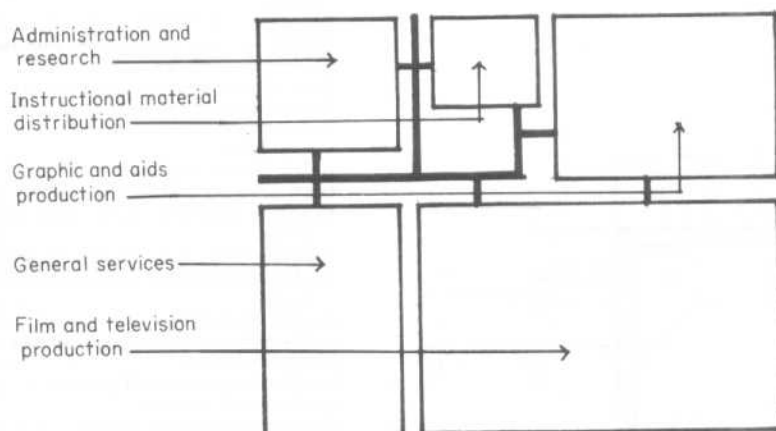

- Lobby and Circulation
Include display, exhibition, reception, kitchen areas
Generous to accommodate many large groups in the building
- Instructional Spaces
Lecture halls (capacity determined by local programming)
Storage and preparation areas
Seminar and small-group rooms

REGIONAL EDUCATION CENTER (SUPPLEMENTARY)

This concept is not new. There are already many attempts to provide regional programs, resources, and services; some are little more than country film libraries while others (like Toronto's Education Centre) provide a whole variety of services, classes, materials, and publications. Title III money will begin to fill in the gaps in our fragmented efforts so far, and the future points toward more "comprehensive" supplementary centers.

Despite the constant use of the term "center," these regional activities may not be accomplished in a central facility at all. The best possibilities for coordination and cross-fertilization exist in the central facility, but economics may preclude this. Many of the programs and

services can be accomplished in outlying or adjacent buildings; most "centers" will probably be a combination of a central building with many of these scattered adjunct buildings housing various parts of the effort.

The types of spaces that might be included in the supplementary center are many, including

- Regional Administration
 - Administrative office and conference areas
 - Clerical staff areas
 - Regional research and conference areas
 - Central records and storage areas
 - Data processing center
- Program Coordination
 - Administrative and staff areas
 - Facilities for the programs themselves
- Resource Services
 - Regional office and conference
 - Professional resource library
 - Search and bibliographic work area
 - Central examination area for books, resources, and equipment
 - Central ordering and processing
 - Central collection of materials for area borrowing

Necessary work areas

- Shipping and receiving
- Production Services
 - Regional office and conference
 - Research, testing, and evaluation
 - Equipment mock-up and repair
 - Radio origination studios and support
 - TV origination and support
 - Film origination and support
 - Photographic and film processing
 - Graphics center
 - Writing and editing publications areas
 - Publications mock-up areas
 - Central reproduction facility
 - Shipping and receiving
- Curriculum Services
 - Regional office and conference
 - Curriculum development and project center
 - Resource rooms for the various disciplines
 - Spaces for adjunct and consulting staffs
 - Student testing area
 - Pupil personnel services staff area
 - In-service training areas
 - Demonstration classrooms
 - Exhibit areas
- Administrative Services
 - Legal advisory office
 - Financial planning, audit, and control office
 - Transportation, maintenance, etc. offices
 - Central personnel interviewing and records center
- Supporting Services
 - Lobby and central exhibition spaces
 - Large-group area
 - Conference and assembly areas
 - Cafeteria and kitchen
 - Central receiving and storage
 - Central workshop
 - Maintenance, toilet, services, etc.

Many of these facility types have already been discussed elsewhere. The design of the regional center will necessarily become a process of "putting them together" with the necessary offices, conference areas, circulation, and other "support" areas.

Figures 1 and 2 show the kinds of space relationships that might exist in a regional center undertaking a broad range of programs and services.

Regional Education Laboratories

While the regional supplementary center can perform services and conduct localized research for its members, there is still a need for educational research on the larger scale. This larger-scale research has been growing steadily in this post-Sputnik era, but much remains to be done. Moreover, overall coordination of projects and widespread reporting of findings are needed if the research is to become an effective part of contemporary education.

These concerns stand behind the creation of the regional education laboratory. The laboratory steps in to undertake the research and fill the gaps always present between projects and dissemination of results.

So far, attempts at these regional research and development centers have been sporadic; some highly successful ones have been set up in large universities to attack specific educational problems, but the educational laboratory concept has yet to be adopted on any scale. Title IV of the Elementary and Secondary Education Act of 1965 calls for aid to support and maintain these kinds of centers, though, and growth in this direction is bound to result.

While these laboratories will take on different tasks, they will have some similar goals in mind, such as the following:

Educational Facilities with New Media, Department of Audiovisual Instruction, National Education Association in collaboration with the Center for Architectural Research, Rensselaer Polytechnic Institute.

COLLEGE AND UNIVERSITY FACILITIES

Regional Education Center

PROGRAM-ORIENTED

Fig. 1

SERVICE-ORIENTED

- To carry on a concentrated and coordinated program of educational research activities. These activities will most likely be accomplished by eminently qualified persons and will have widespread rather than limited application and use.

- To develop new curriculum units, with special attention to ways of supporting them. This will make media research, testing, and evaluation an important part of the laboratory's program.

- To test, evaluate, and disseminate innovations on a broad scale.

- To provide direction and to encourage innovation in other quarters.

- To supplement and coordinate research throughout the region.

- To provide a training ground for educational research personnel.

In order to achieve these goals, the various regional education laboratories will have a number of common characteristics,

- Projects may be undertaken "in-house" or in collaboration with other educational and community groups.

- Staffing will include at least a corps of administrators to coordinate activities, a professional evaluation staff, and a professional dissemination unit. Actual project research may be carried on by other staff members, interim staff, consultants, or a combination of these.

- The laboratory will remain flexible. It will adapt to the situation as necessary, changing its own character as it undertakes different kinds of projects in different fields.

The regions covered by these laboratories will be necessarily large; some now envision perhaps a dozen large centers around the country. Smaller, more specialized units in colleges and universities may supplement the laboratories or extend their work into specific areas.

Implications for facilities, then, are not concrete. Most laboratories will require a variety of spaces, some of which may be "eked out" of local college buildings or those of other co-operating groups. While many of the laboratory's activities may be scattered around the region it serves, it is reasonable to believe that there will be at least a central administrative facility and staff. Kinds of facilities may include

- Administrative and Project
- Central administrative offices
- Conference areas

Small project offices closely tied to central media and information complexes

- Central Information Complex
- Warehouse of resources, reports, data files, etc.

May include information retrieval and storage

Entire complex readily accessible to all in the center and wired to adjunct units of the laboratory

- Central Media Complex
- Production and origination facilities as required

Work areas for testing and mocking-up media units

Accessible to all functions in the laboratory

Can be used for media research and support for other research

- Evaluation and Processing
- Office and conference area for the evaluation team

LOWER LEVEL

UPPER LEVEL

Fig. 2

COLLEGE AND UNIVERSITY FACILITIES

Regional Education Center; Resource Facilities

- Data processing center serving all units of the laboratory
- Demonstration and Mock-up
 - Area for mocking-up different facility types
 - Large open space that can be arranged in many ways
 - Central location for access by staff, students, visitors
 - Provision for visitors and viewing
- Dissemination Area
 - Office area for professional dissemination staff
 - Publications editing and mock-up areas
 - Printing and finishing areas
 - Shipping and receiving
- Service and Workshop
 - Large workshop to serve for all "carpentry" activities in the laboratory
 - Conventional building service spaces

RESOURCE FACILITIES (LIBRARY)

No other educational facility is receiving more attention today than the library and its descendant, the resources center. There are many concepts and philosophies for the new form of the library, and as is appropriate in a time of change and innovation, the form of the library is certainly not set. One fact is certain; the library (it will be called the resources center from here on) is more than a repository for books and printed materials available for checkout or for use by students at long, drab tables with stiff chairs. The functional characteristics of the library are still present—the acquiring, cataloging, indexing, storing, retrieving, use, and restoring of information, but the information has taken on many new forms. It is in the form of books, periodicals, and standard references, but also films and slides, audio tapes and programs, videotapes and kinescopes, film strips and miniaturized equipment. The problem is how to handle these various types of resources logistically and still have them readily available for student use as required by the educational philosophy of the institution. (See Figs. 1 and 2.)

It is certainly the educational philosophy and the way it is translated by faculty and staff that dictate how a resources center is used. It may be simply a more complex library—a place where students come and check out materials as required to complete assignments. It may also be the whole focus of the educational program for the institution—a place where a student comes and learns independently, and a place from which information is delivered to students throughout the entire school plant working in a number of different learning situations. More and more, the resources center is becoming the focal point, philosophically and physically, for many new school plants. Whatever the philosophy, it must be spelled out in terms of educational objectives before any architectural planning can begin.

A resources center may function as part of the system of education within a school plant in a number of different ways. Figure 3 indicates a "little school" or "school-within-a-school" concept in which each subdivision contains a

Educational Facilities with New Media, Department of Audiovisual Instruction, National Education Association in collaboration with the Center for Architectural Research, Rensselaer Polytechnic Institute.

Fig. 1

Fig. 2

resources center, either discipline-oriented or general in content. In such an institution, the resources center will contain independent study facilities and seminar and project rooms, as well as the resources themselves. These resources centers may be interconnected for call-up of material from any one of them, and in turn, all the resources centers may be connected with a large, regional electronic storage and retrieval facility.

Figure 4a indicates a single resources center as the focus of the school and serving the entire school. Not only would students come to

Fig. 3

COLLEGE AND UNIVERSITY FACILITIES

Resource Facilities

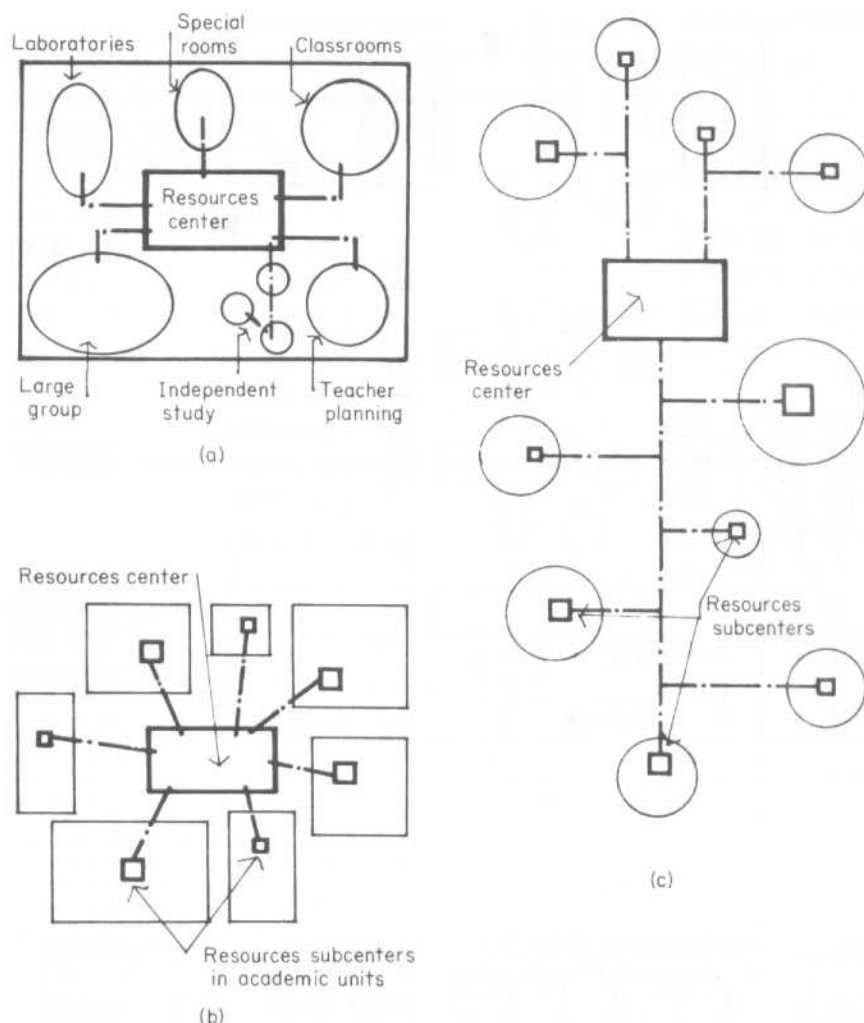

Fig. 4

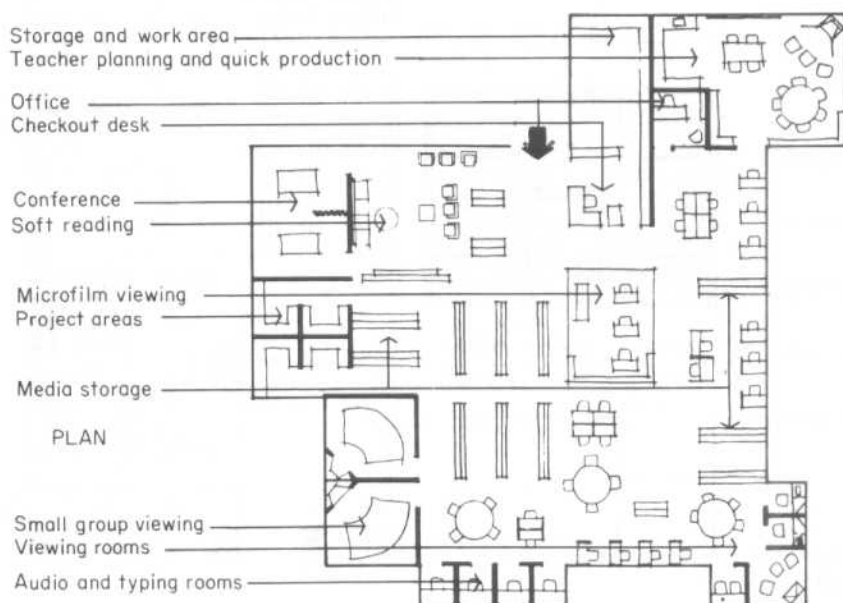

Fig. 5 Resources center.

the resources center to use the resources, but audio and video materials would be distributed from the center to carrels and independent study facilities, classrooms, seminar rooms, and other kinds of spaces throughout the school plant. In this case, a student does not have to come physically to the resources center to partake of its resources.

Figure 4b might illustrate a large educational complex—a college or university, an educational park, or a large, centralized school plant. A large central resources center serves the entire complex and, in turn, a number of subcenters located within specialized academic units. Here resources will be distributed in a number of ways and the student will have the choice of either using his local subcenter or going to the larger centralized facility. In turn, the central unit could draw from large regional or national information centers.

In Fig. 4c a central, electronically based storage and retrieval facility serves a number of schools within a district, and each school contains a small resource subcenter. It should be noted that in this type of system all materials must be distributed electronically or physically from the central facility to the schools for student use.

In programming and planning resource facilities, the following points may prove of assistance:

1. The resources center in school buildings should be considered as a learning facility as well as a place to store and use materials. This means that the spaces must be readily accessible, inviting in character and environment, well equipped, humanely administered, and an integral part of the school plant.

2. Independent study and learning facilities within or associated with resources centers are more than "electronic carrels." A comfortable lounge chair, some carpeted flooring, a seat at a table, tables with low dividers, small separate rooms, and writing cubicles are all independent study facilities and should be represented along with the electronic carrel. There should not be a choice of only "wet" or "dry" carrels, but a mixture of these and other accommodations for individual students learning with resources.

3. A concern with space utilization has led to some solutions for independent study facilities in resources centers that consist of monotonous row upon monotonous row of carrels. Such planning seems to completely deny a basic philosophy of the resources center—individualization.

4. In bringing a resources center to physical reality, it may follow a variety of solutions—centralized in a single large space, decentralized in small units which are dispersed about, or a combination of both. Whatever the planning scheme, the resources center will include a number of common components. These would include administrative and work areas, media storage, book and periodical storage, soft reading area, independent study area, simple production and reproduction facilities, and conference, project, and seminar facilities.

5. In planning a resources center, consideration should be given to the rapid advances that have been made in computer-based library operations—processing acquisitions, printing out bibliographies and special lists, handling checkouts and due and reserve notices, and requisitioning materials. Certainly this type of system should be studied with the idea of initially incorporating compatible components allowing expansion of the basic system serving several centers and subcenters.

6. Electronically based information storage and retrieval systems will certainly be a

COLLEGE AND UNIVERSITY FACILITIES

Resource Facilities

planning factor in designing resources centers. Some carrels will be "wired into" such systems for instant access to information, and in some cases, the resources centers may be part of the "input" into a retrieval system. The hardware and economies of such systems have not been clearly defined, and they are not universally available. However, planning must anticipate their eventual role.

Resource Facility Study—1

This resources center combines many different types of facilities into a single center. As such, it would form the resources focus for a high school, middle school, and, with modifications, an elementary school. In addition, it has many of the characteristics appropriate for a resource subcenter found at many points in a large educational complex.

The central area consists of storage facilities for books, media, independent audiovisual equipment, and a variety of facilities for independent study and learning—soft reading areas, electronic carrels, reading and writing carrels, reading tables and chairs, etc. Surrounding this center are a number of significant supplementary facilities. Small viewing rooms provide for independent and team work using projected media. Typing or audio rooms provide soundproof cubicles for individual use. Seminar rooms, project areas, and conference facilities all provide for the use of various kinds of resources by small groups working together. Naturally, storage, workrooms, and office facilities must be provided, as well as reference files, indexes and a control center. Finally, the teachers' planning, preview, and simple production facility is provided as part of this particular resources center. (See Fig. 5.)

This center would be located at the heart of a school plant with other educational facilities surrounding it, all easily accessible.

Resource Facility Study—2

This resources center would be appropriate as a subcenter in "schools-within-schools." It can be either a general resources subcenter or discipline-oriented, and provides for long-term, independent student utilization. Carrels for audio and video use, and reading and writing, are provided, as are a soft reading area, tables and chairs, and enclosed and semi-enclosed rooms used for typing and recording. The adjunct facilities include small group viewing rooms, project rooms, conference rooms, a small teacher production facility, and office work and storage space for the administrators of the center. (See Fig. 6.)

As a resources subcenter, this facility would be surrounded by other types of learning spaces, and the line of demarcation between the resources and other educational facilities would be indistinguishable. In fact, if properly designed, students would move between these spaces freely without feeling that they were moving from one educational world to another.

Resource Facility Study—3

This resources center introduces the basic philosophic concept that teachers themselves are significant resources and coordinators in the use of resources. Therefore, they should be part of the resources center, and this study includes a teacher planning and conference suite composed of teachers' work cubicles

Fig. 6

Fig. 7

COLLEGE AND UNIVERSITY FACILITIES

Resource Facilities; Large-Group Facilities

surrounding a common conference and work area. Here students may come on appointment, or on a "drop-in" basis, and consult with their instructors as readily as they could consult with the other resources contained in the center. This type of facility would be most appropriate for a non-graded or continuous-progress type of educational philosophy. It might serve either as a resource subcenter in a "school-within-a-school" concept or as the basic resources center in a school which is moving toward continuous progress, but which is initially designed for a significant program in team planning and teaching. (See Fig. 7.)

The remainder of the resources center includes accessibility to a variety of resources which may be used individually and in small groups.

LARGE-GROUP FACILITIES

It seems that the effectiveness of media in education has been tested most extensively in large-group learning situations. Certainly in the last ten years many public schools and a large number of colleges and universities have adopted large-group instruction using media for an increasingly large proportion of the instructional load. In fact, it is through the utilization of learning media that large-group instruction may become truly effective—by bringing to this type of learning system means for magnifying and displaying information, presenting information from a remote location, introducing information that otherwise would be impossible to present, and introducing information in a more demonstratively effective way.

There is a current reexamination of large-group instruction following on the heels of a general concern for more independent and individualized learning experiences. Even though there are proponents of each to the exclusion of the other, the logical solution for most institutions will be the incorporation of both types of learning experience—and indeed a variety of learning experiences in between—and in turn the necessary facilities for their effective use. This "mix" of learning experiences is the basis for many organizational patterns, and is at the heart of the systems approach to designing learning.

For these reasons an examination of the planning of large-group facilities with media is essential, particularly because the design criteria and planning considerations in large-group facilities with media are probably the most critical of any type of space that might be provided. The following points summarize these design and planning criteria:

1. An optimum viewing area, as defined by the various display surfaces which are considered critical for student viewing, will deter-

mine the most effective room shape. This optimum area is not a fixed function of the combination of screens and/or monitors but will vary with the type of material presented, the duration of the presentation, the quality of the equipment, the type of screen, and other factors of environment. (See details of projection systems and viewing areas.)

2. Stepped or sloped floors will always be required in order to provide optimum viewing conditions. Both horizontal and vertical sight lines in these rooms are major design factors. Also, raised seating introduces more intimacy in these rooms and may allow the interaction desired for case presentations and discussions.

3. Once the viewing area has been established, the actual capacity of the large-group space becomes a function of the seating type and arrangement. Seating types run the gamut from loose seats to fixed seats and built-in counters. Whenever possible, aisles and circulation spaces should be kept out of the viewing area to assure the maximum number of seats located within optimum viewing conditions.

4. As long as the display of information and the use of media are a significant function in the large-group room, windows and natural light are a liability rather than an asset. Although means may be found for controlling natural light, the size of required images in the room mitigates against natural light with its inherent problems of control and "washed out images" caused by ambient light.

5. Complete climatic conditioning is necessary for this type of space by virtue of the number of students involved, the lack of natural windows and ventilation, and the concentration required by this type of learning experience. Such conditioning will include cooling, air change, filtration, and humidity control.

6. Proper acoustical design, from the outset, is necessary for the successful functioning of this type of room. Not only should sound originating within the room be easily heard by all students but the space should be thoroughly acoustically isolated from interfering sounds from the outside.

7. Likewise, the planning of lighting is an important consideration. Generally, three levels of illumination will be necessary for the display methods used in these spaces; control of ambient light on projection screens is likewise essential.

8. Because lighting, acoustics, and climatic conditioning are such critical design features in the large-group room, their integration and design must be considered from the outset. Too often this kind of space suffers badly because these design features are neglected until too late in the planning process.

9. Educationally, the key to the proper functioning of this type of space is the integration of the systems for displaying information and other media uses. The studies which follow illustrate the fact that the display surfaces are an integral part of the room, and that equipment should be located for proper functioning and not to interfere in any way with the process of learning. This consideration includes the location and planning of the teacher's lectern or control center and suggests that lighting and equipment be tied in and controlled from this lectern.

10. Finally, the success of these rooms will depend on the inclusion and relationship of adjunct storage, projection, and preparation areas. This is particularly true when rooms are to be used for science courses requiring equipment and demonstrations. In addition,

these adjunct spaces may include project areas, conference rooms, and other smaller-group activities used to complement large-group presentation.

Large-group instruction can include learning functions other than the simple presentation of information. Manipulative and laboratory types of experiences have been employed for many years, and this study suggests a combination of laboratory and lecture-demonstration functions within the same facility. The resulting "lecture laboratory" permits the experimental and information presentation functions to be carried on simultaneously and without changing rooms. The advantages of being able to demonstrate and present information to a group of students seated at laboratory stations is one that may help overcome the problems of amalgamating media and instruction in science areas.

The lecture laboratory is a suite of facilities including a large area containing over a hundred student laboratory-desk stations, two smaller demonstration and special equipment areas, a rear projection area, a special projects room, and storage and preparation space serving all parts of the facility. The student area is arranged on three platforms with a ramp at one side for wheeling in special equipment, reagents, and other materials for student use. Each laboratory station consists of a stand-up, sit-down work area with complete utilities serving every two students. The smaller demonstration areas in the front of the room permit small groups of students to work more intimately as a team or with an instructor, and also provides space for special equipment used by students during the laboratory exercises; these can be shielded from the larger area by movable partitions. (See Fig. 1.)

The projection area allows two 10-ft images to be projected simultaneously, and further information display can be provided through two overhead projectors. The front of the room also provides area for demonstrations which are prepared and supplied from the adjacent work and storage room. These types of demonstrations will probably be magnified by closed-circuit TV and projected on the rear projection screen.

Production-Support Facilities

To reiterate a basic point, the effective and efficient utilization of learning media in education requires three broad types of space—learning spaces, resource facilities, and production-instructional support facilities. In addition to classrooms, lecture rooms, laboratories, and seminar rooms designed and equipped with appropriate media, it is necessary that film, slide, and tape materials and other media resources be made accessible to students and staff for individual use. Also, facilities must be provided in which learning media may be produced and which house the staff and functions that support the teaching faculty in their work.

The following points are offered as guidance in the design and planning of production-instructional support facilities:

1. Production and support functions and in turn their facilities vary in complexity and size with their location and level within the educational system. Within an academic department or "little school," simple facilities should be available for teachers and students to produce transparencies, photocopies, slides, multiple copies, graphs, and charts. Usually, this local, simple production area will be located within

New Spaces for Learning: Designing college facilities to utilize instructional aids and media. Report of Research Project DASFE: (Design of Auditorium-Studio Facilities for Engineering Education) supported by grant from Educational Facilities Laboratories, Inc., revised ed., June 1966.

COLLEGE AND UNIVERSITY FACILITIES

Large-Group Facilities

Fig. 1

the resources center or instructional materials center.

At the other end of the spectrum may be a very large and complex production facility as part of a large regional service and production center. Such facilities may form a part of the regional service center or educational laboratory. In between these two extremes are production centers which will serve a university, a college, a large high school, several schools within a district, an entire school district, or

all the institutions located in an educational park.

The important objective is to provide several echelons of production and support ranging from the very large and complex covering a region to the very simple and local serving a few teachers. Also, to adequately support the uses of media, all of these echelons of production and support should eventually be represented so that the instructional staff has many levels to draw upon, depending on

the complexity and needs of the particular learning situation.

2. Production support centers may be composed of a variety of components, each of which is related according to the echelon of production and the types of services to be offered. Some of these components are:

- Graphic arts production
- Photographic production
- Motion picture production
- Audio recording
- Animation
- Television origination
- Television control, distribution, and recording
- Film editing and processing
- Graphic materials production and assembly
- Scene, set, and model production
- Equipment storage and repair
- General storage
- Administration and offices for production staff and visiting faculty and teachers
- Conference and preview facilities
- Film and tape materials and equipment storage and distribution.

In programming an instructional support center, it is the manner in which these components are arranged and placed together that creates the appropriate center for a particular institution.

3. The instructional support center can perform several major services in addition to producing films, slides, tapes, and other instructional materials:

- It can design and produce materials that are not commercially available but which are needed for specific instructional purposes.
- It can provide technical assistance to teachers and professors in using instructional technology effectively. It is this type of assistance which helps teachers overcome a fear of mechanical devices about which they have little knowledge and great anxiety.
- It can be the catalyst which causes teachers to begin planning instruction and learning together. Producing televised instruction may bring cooperation among teachers who otherwise would always function as independent entities.
- An instructional support center can provide pedagogical assistance to teachers in designing learning. The learning systems designers—the pedagogical consultants—would logically be housed within this center.
- These facilities can provide the professional focus for teachers and faculty members by making available professional references, material, journals, and consultants.

4. Instructional support facilities may be an integral part of an educational plant or a separate, free-standing building or unit. In either case, consideration should be given to designing the area to permit changes in areas and relocation of walls, services, and cables. Flexibility of this type is very important, as the functions, staff, and faculty develop. A "loft space," free of interior partitions and permitting economical changes, may be the best type of space.

5. One of the changes anticipated above involves the planning of TV studios. Often when studios are initially planned, the faculty will wish to provide for a class of students to be present in the studio during production. However, as the faculty becomes more comfortable with television, the need for students in the studio is less significant. The building should be designed to permit this evolutionary change.

6. Obviously there is not single instructional

COLLEGE AND UNIVERSITY FACILITIES

Large-Group Facilities

support facility which solves all needs at all levels. There are many, many different systems of production and support which can be diagrammed. Figure 2a indicates a regional center which supports a number of subcenters within schools throughout the system. From the subcenter, further production and support activities are provided to individual classrooms, resources center, independent study facilities, and special rooms. It should be noted that within the resources center there is the small, simplified production area for teacher use. The same diagram might illustrate the activities within a college or university campus where, from a central location, major production and support feeds out into schools and departments and then into individual facilities and areas.

Figure 2b illustrates a center within a large central school which not only supports that school but feeds into other, smaller schools throughout a school district. This might be the appropriate diagram to illustrate production-support facilities within an "educational park."

Production-Support—1 This production-support center might serve a high school, a couple of middle schools, several elementary schools, or a combination of all. Figure 3 shows the basic facilities to support uses of television, graphic arts, and projected media while providing the administrative and instructional support activities necessary for such a situation. The multi-use studio can be used for live and recorded television production, film production, still photography, and, possibly, audio recording. Control of all of these production activities would come from the central control and distribution room.

The graphics room includes drafting space, copying machines, film editing and copying equipment, assembly and work tables, and other equipment associated with these types of production. The preparation and storage area adjacent to the studio is used for building and storing sets and models; next to it is maintenance and repair area for AV equipment used both within this production facility and throughout the schools it serves. The administrative facilities include waiting and exhibit areas, preview and conference rooms, and offices.

Production-Support—2 Figure 4 illustrates a center producing basic institutional aids and media, with an emphasis on film production. The production process is initiated by a conference between faculty and production staff, at which time the nature and instructional requirements of the materials are defined and a production schedule is set up. After production, the finished materials are distributed to the faculty concerned. Eventually the material may be deposited in the library of resources center where it is available to the student for review; it may also be distributed to cooperating institutions.

Production-Support—3 Figure 5 illustrates a center designed for originating televised instruction for distribution to a number of receiving points on the campus or to cooperating institutions. This center may fulfill a number of related functions such as reception and distribution of "off the air" programs, recording of televised instruction (videotape or kinescope), distribution of film materials, and coordinating of remote origination from labs, research centers, and other potential "studios." These related functions affect space considerations only as far as requirements of engineering

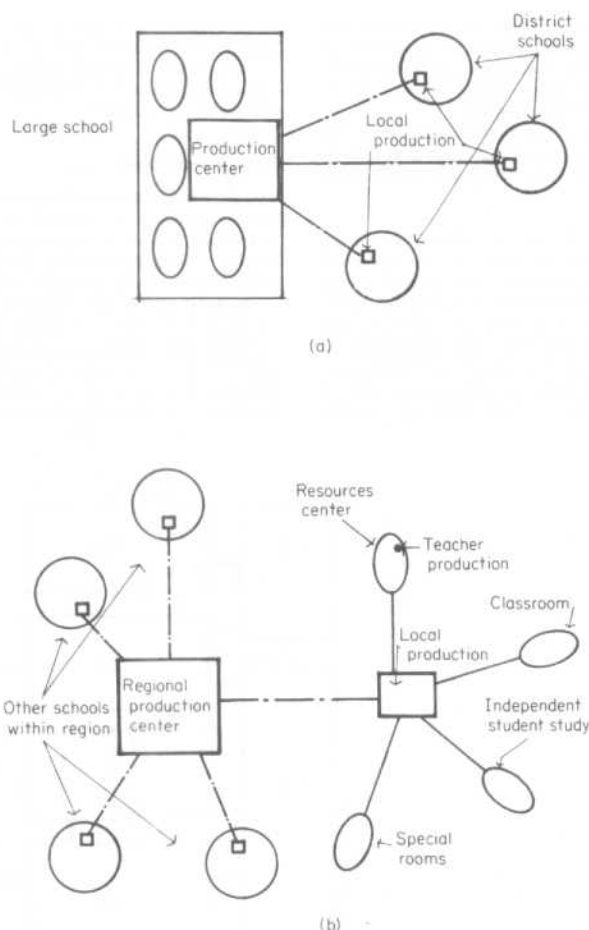

Fig. 2

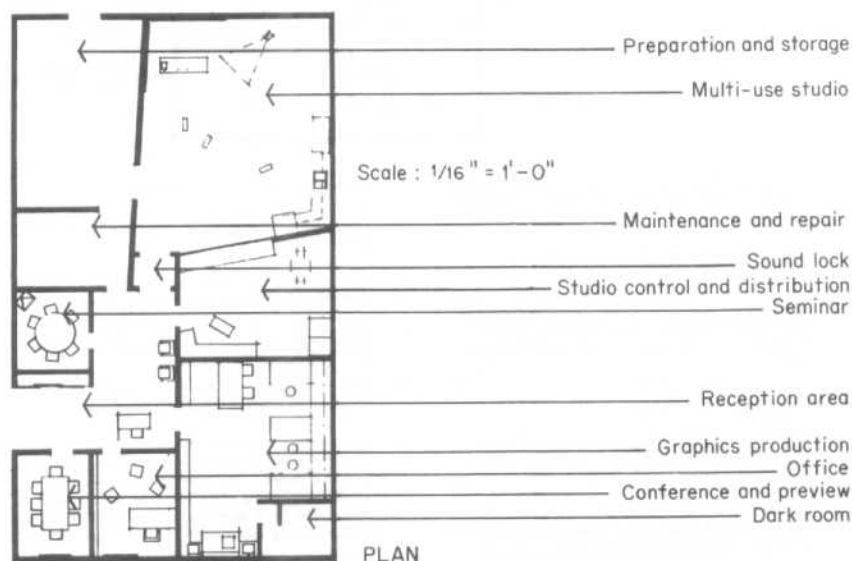

Fig. 3

COLLEGE AND UNIVERSITY FACILITIES

Large-Group Facilities

and control, and storage of materials and equipment. Distribution of the television image may be by open or closed circuit or both; the method of transmission does not basically affect the design of the facility.

Such a unit would probably serve an entire campus, or, possibly, in the case of the large university, one or more colleges on the campus.

Production-Support-4 An institution venturing into a broad program utilizing the aids and media may well consider providing a single facility that combines all the production functions. In the long run such an approach can probably be justified from the standpoint of economy of space, equipment, and personnel, as often a single activity will support several production processes. A graphic arts studio,

for example, can produce not only visuals and graphic materials for direct classroom use but also the materials used in film production and television production. This total, more complex center is represented in Fig. 6.

Projection Systems

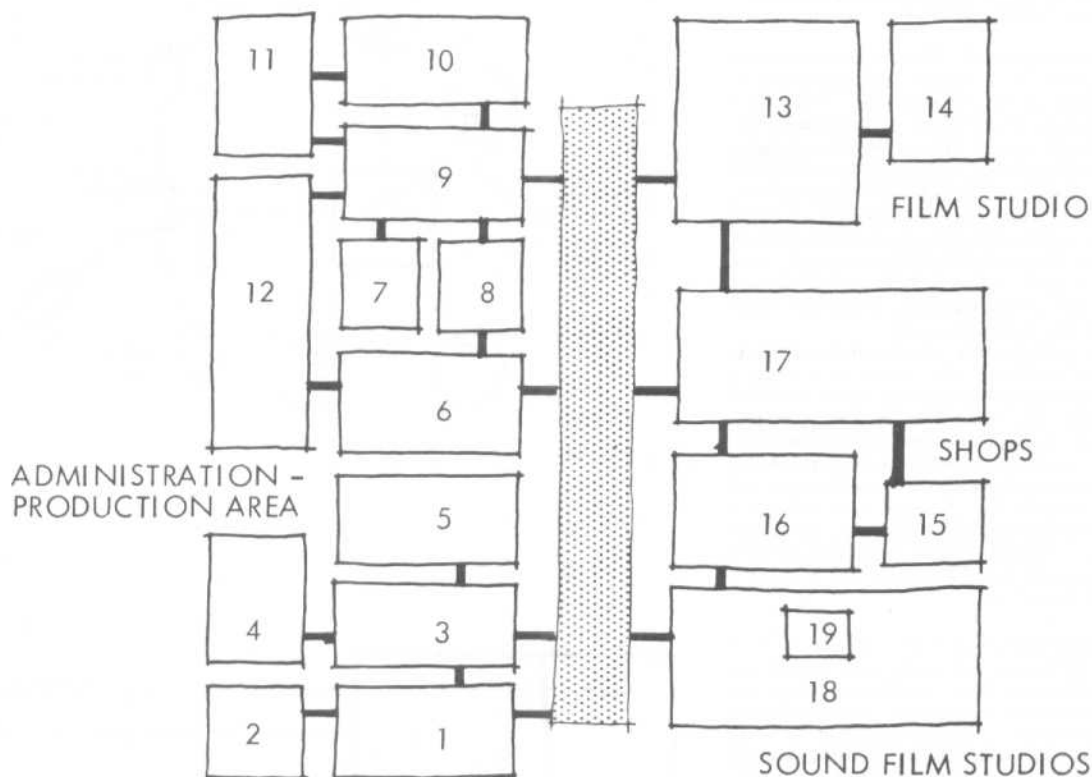

Too frequently the hardware used in audiovisual presentations is regarded as a collection of individual items—a projector, a screen, and a speaker—each performing its function more or less independently. A much broader concept is essential if media are to be used with maximum effectiveness. Not only these hardware items but also the seating area and the environment itself must be considered as integrated components of a system, each influenced by and depending on all of the others in producing the

total effect. None of these components, even the hardware, can be selected on its merits alone.

Regardless of the projected material or method, the effectiveness of the presentation depends upon the ease with which the viewers receive the message. With any normal audience, the quality of viewing conditions is chiefly determined by four factors:

1. The appropriateness and efficiency of the projection equipment and screens
2. The quality of the projected material
3. The location of the viewer in relation to the screen
4. The visual and auditory environment

Front and Rear Projection Before considering any of the above matters, it is important to recognize that two different methods may be used

1. clerical and shipping - location of receptionist, secretaries and personnel involved in distribution of materials.

2. film vault - storage of completed film materials.

3. conference-rehearsal - rooms for faculty-production staff conferences, rehearsals prior to recording or filming, and periodic staff conferences.

4. production staff offices.

5. recording and radio studios - making of audiotapes, dubbing of sound on films and possibly radio broadcasting.

6. graphic-art studio - production of graphs, charts, "visuals" and some slide materials for both direct classroom and film production use.

7. still photography.

8. animation - filming of art work.

9. processing - darkrooms for limited developing and printing of film materials.

10. editing-assembly - editing of motion pictures and assembly of all instructional materials.

11. previewing - small projection rooms for viewing incomplete as well as finished film materials.

12. offices, storage, and toilets - located as needed adjacent to the various production areas.

13. film studio - a large, open studio for the filming of silent motion pictures on which the sound may later be added. The studio can be flexibly divided into filming areas by using demountable flats. This will permit simultaneous filming of one or more productions.

14. external slab - concrete slab (possibly covered) adjacent and accessible to the studio for exter-

nal filming. It may also be used as a receiving platform for materials taken directly into the studio.

15. model and set shop - production of models and demonstration apparatus for direct instructional or production uses, and the making of sets and flats for use in the studios.

16. storage - a large area for storage of materials used in the studios or awaiting distribution for classroom use.

17. equipment receiving, storage and maintenance.

18. sound studios - several studios in which both the sound and image are recorded simultaneously. This permits only one production at a time per studio.

19. control-engineering - glass-fronted booths accessible to each studio for control-engineering personnel and equipment.

Fig. 4

COLLEGE AND UNIVERSITY FACILITIES

Large-Group Facilities

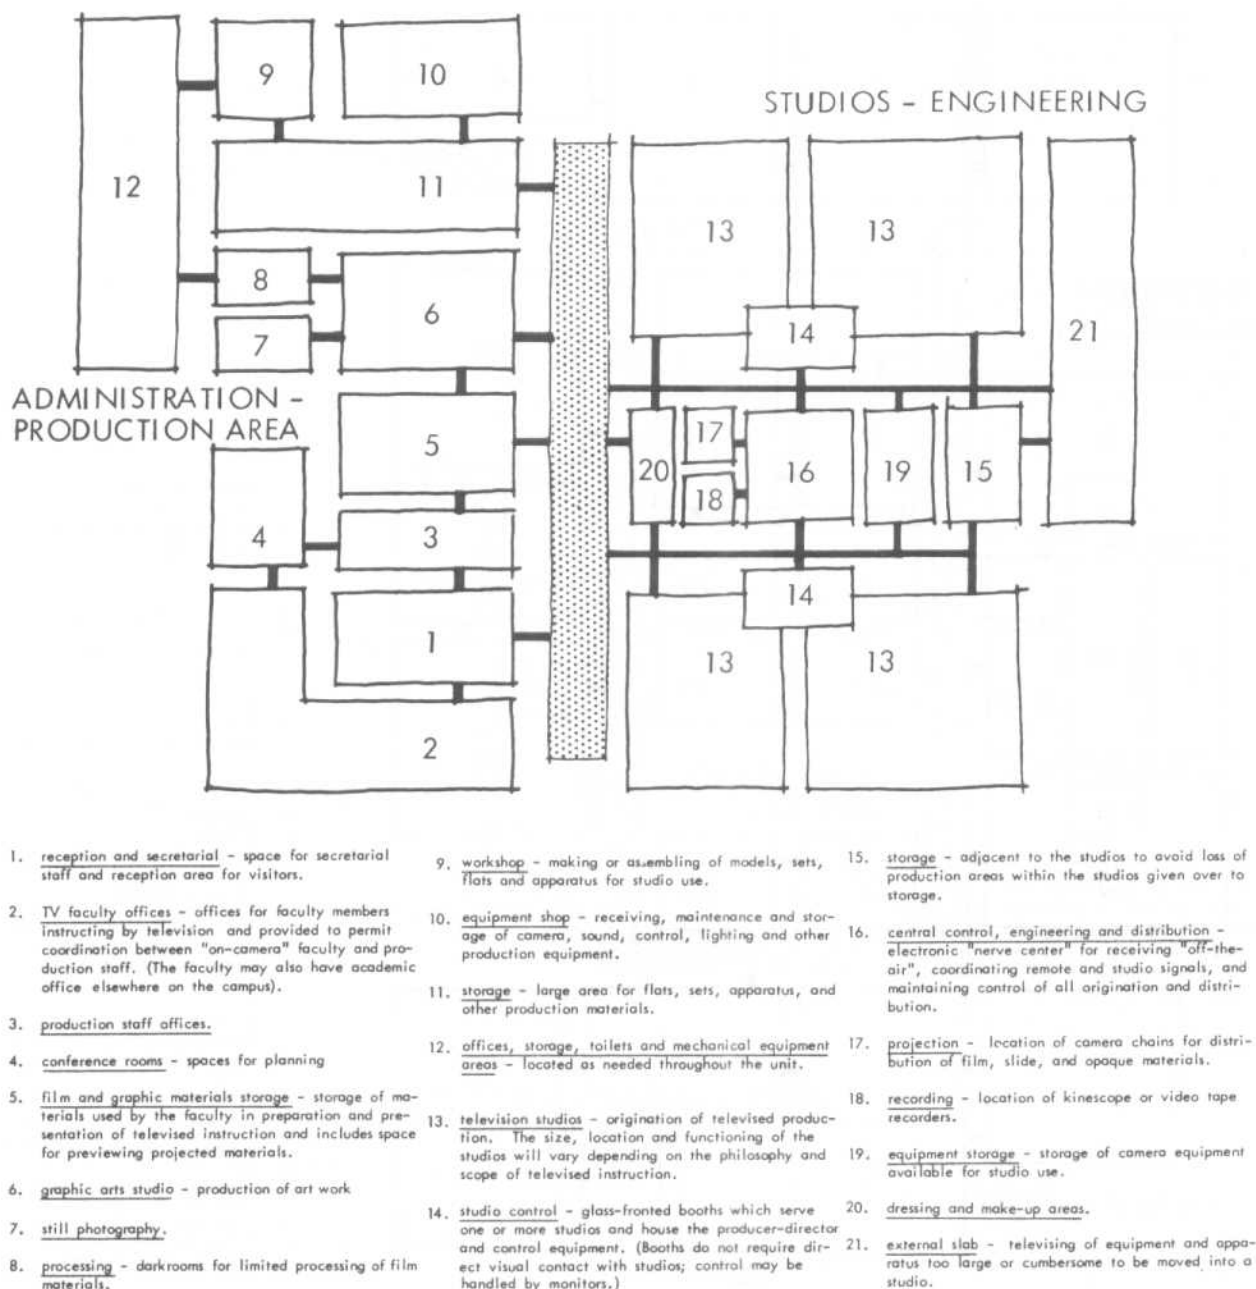

Fig. 5

for projecting images onto a screen, and that the choice of method will influence the design of a projection system. These two methods are:

- Front projection, in which both the projector and the viewers are on the same side of an opaque screen which reflects the image, and,

- Rear projection, in which the projector and the viewers are on opposite sides of a translucent screen upon which the image is displayed.

Either one may be used for any type of projector, including the TV projector, but customarily the overhead and opaque projectors are used in front projection. (See Fig. 7.)

Both front and rear projection have their inherent advantages and disadvantages, which become clear by comparing them in respect to the most important areas of difference. These are:

- The effect of ambient light
- Space requirements, and
- Interference with the projected image

The ambient light level in the room is much more critical with front projection than with rear projection. This means that with present equipment a much higher level of room lighting can be tolerated in the viewing area when rear projection is employed. This is considered to be the chief advantage of rear projection,

particularly in larger rooms. In rooms where small image sizes are appropriate, ambient light effects may not be critical providing proper equipment is used. Current developments in the improvement of equipment indicate that the size of acceptable images possible with front projection under useful levels of ambient light will be increased.

An undeniable disadvantage of rear projection is that additional space behind the screen must be provided to accommodate the projectors and their throw distances. To conserve space, projectors with short focal length lenses are desirable and mirrors may be used to "bend" the projection rays. Also self-

COLLEGE AND UNIVERSITY FACILITIES

Large-Group Facilities

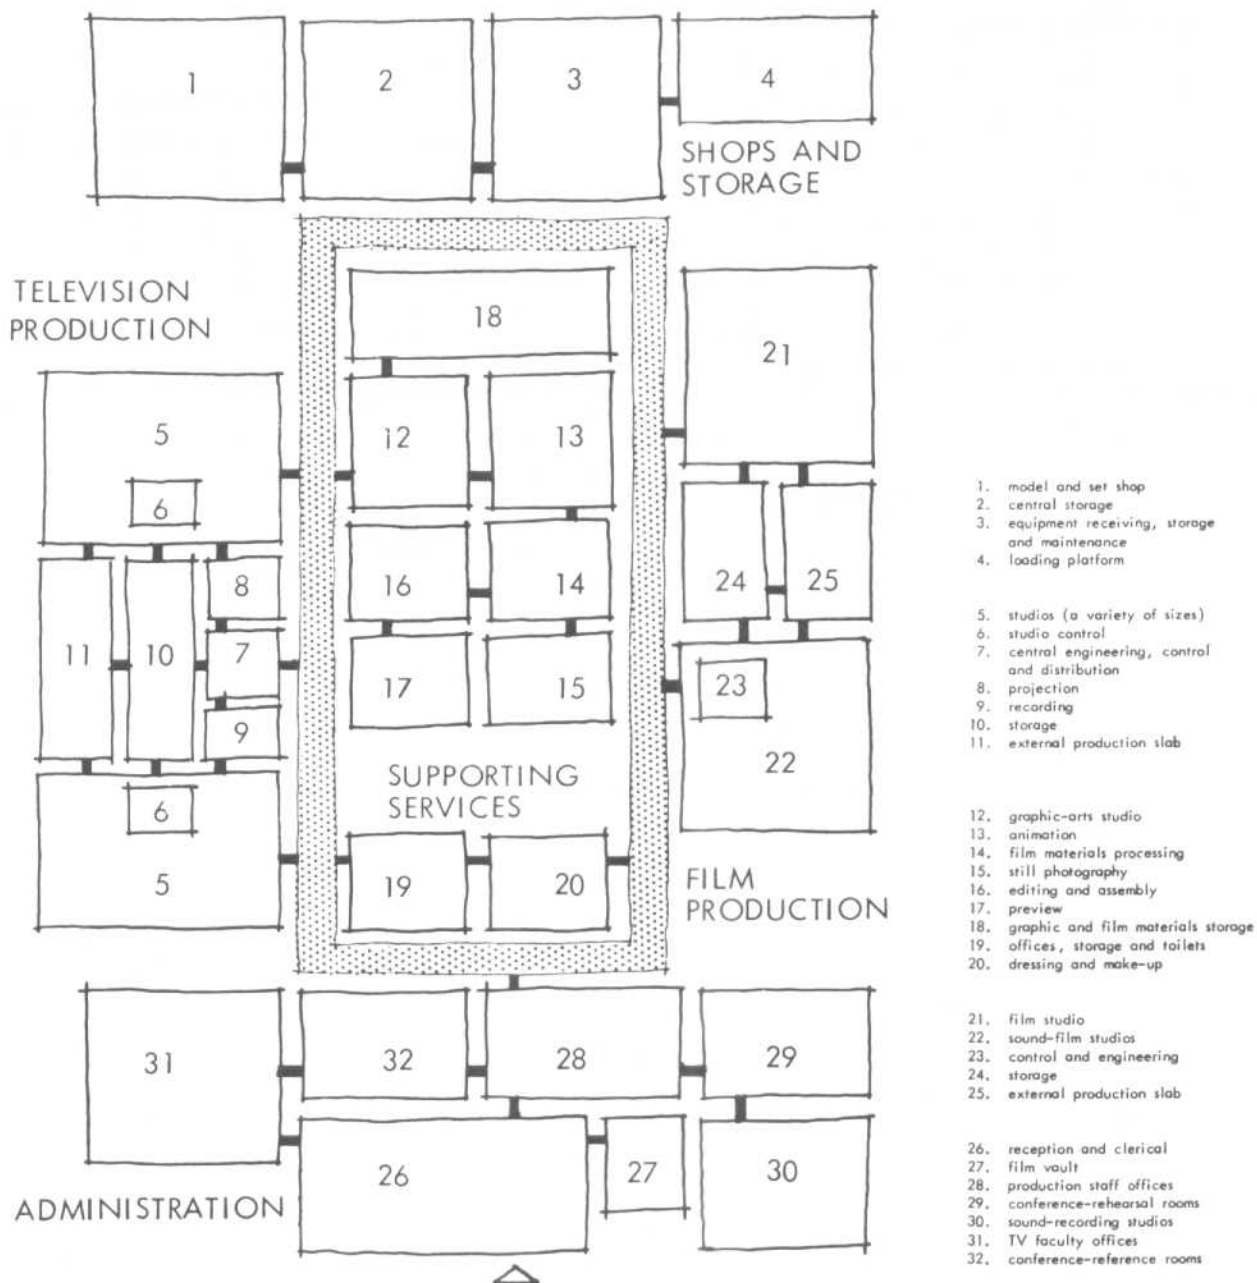

Fig. 6

contained screen-projector units or media modules may be used. It must be recognized, however, that shortening the focal length of the projector decreases the width of optimum viewing areas, and the use of mirrors generally diminishes the effective brightness of the projected image.

One of the important advantages of rear projection is that the projection rays are protected from interference by either the instructor or the viewers. The instructor can stand in front of the image to point out details without casting shadows. With front projection this is impossible; distracting shadows are cast by any object or person in the path of the projection

beam, and the freedom of the instructor is limited accordingly.

It has been assumed that in both methods the projectors are located in reasonably sound-proof enclosures and that remote control is provided for the instructor who remains at the front of the class. Such assumptions are frequently not valid for front projection, however. With relatively small groups of viewers, portable front projection equipment is often used, and the instructor himself may operate the projector. Used in this way, front projection has several additional disadvantages which should be recognized. Unless precautions are taken to minimize it, the noise of the projector

is distracting to viewers, and if the instructor must double as an operator, his effectiveness as a teacher is necessarily diminished.

Screens The design of any projection system must necessarily recognize "the human factor"—the needs and limitations of the observer. The impact and effectiveness of the image displayed largely depend on such matters as its brightness, its legibility and its contrast values.

The human eye can tolerate and adjust to a remarkably wide range of conditions, but if eyestrain is to be avoided, these critical variables must be controlled within established

COLLEGE AND UNIVERSITY FACILITIES

Large-Group Facilities

Fig. 7 (a) Front projection; (b) rear projection.

limits of acceptability. The projection screen is a major component in determining visual comfort.

A variety of screen types are available for both front and rear projection. They differ significantly in their characteristics, affecting both the appropriate size of viewing area and the tolerable level of ambient lighting.

Projectors The reader is cautioned that any discussion of projection devices can only report on the existing ranges and characteristics of commercially available equipment. Technological developments can render much of today's equipment obsolete; at the time equipment is selected, the newest models should be investigated for improvements in optical systems, lumen output, remote capability, ease of operation, and cost.

Overhead Projector. The overhead projector currently is one of the most popular projection devices in classrooms. Ease and speed of transparency-making, high lumen output, elimination of the need for room darkening, and ease of operation are among its good characteristics. The only special requirement for this projector is a tilted screen in order to prevent keystone of the image. Projectors range from fanless desktop models to those which include the projection of slides and filmstrip through the projector's optical system.

35 mm Slide Projector. The classroom use of 35 mm color slides has substantially increased with the production of inexpensive,

foolproof 35 mm cameras and remotely controlled projectors. With the low cost of slide production and the space savings in storage, the 35mm slide is being used more and more extensively than the 3½-by-4-in. slide. For efficient use in classrooms, the projectors should be capable of remote on-off, forward-reverse, and focus. Ideally, the fan should have a thermal device to allow cooling of the projector after the lamp is turned off. Highly desirable characteristics for a projector will be ease of loading, low cost of slide trays that accept all sorts of mountings, and freedom from jamming. Lenses are available that will allow projection from as short a distance as 1 W (1 width of the screen) for rear projection to 6 W for front projection in larger auditoriums. With improvements in lumen output, mirrors can be used to reduce the space required for rear screen projection. Projectors are available with xenon light sources, random access, digital readout, and audio projector programming.

3½-by-4-in. Slide Projector. Most 3½-by-4-in. slide projectors manufactured today are of the manually operated type. For the purpose of this report and where remote control of the projection device is necessary, the few remotely operated projectors currently available are discussed. Some of the most desirable characteristics of these projectors are high lumen output, the capability with an adapter of projecting 35 mm slides, the ability to handle polaroid slides, and short-throw lenses for rear screen projection.

Motion Picture Projectors. Currently the 16 mm projector has a monopoly on motion picture projection in the classroom. However, with the introduction of the new, large-frame 8 mm film and sound cameras, there may be a marked changeover to 8 mm for small-group use, and it will be introduced for independent study. Film projection using 35 mm film has never found extensive educational application.

Film Strip Projectors and Previewers. The low cost and availability of film strips on almost every subject make this form of visual aid attractive to many teachers. Projectors with remote control are required for rear-screen projection. Simple film strip previewers may adequately serve the student studying independently. In between are projectors appropriate for front projection with small groups.

Television Projectors. Television projection has its greatest implications for large-group instruction. Its use as a method of displaying and magnifying gross images is excellent. Its promise as a first-rate teaching tool is dependent not only on its ability to have good contrast, brightness, and definition but also simple maintenance. Projectors are available for closed circuit or broadcast in either black and white or color and black and white. In general, the more expensive the projector, the more acceptable the image and the higher the lumen output. Projected television requires slightly more than a 2 W throw distance. Prices vary tremendously from \$2,800 to \$50,000 or so.

More Information. For more comprehensive information on projection equipment the reader is directed to the *Audio-visual Equipment Directory*, National Audio-Visual Association, Inc., 1201 Spring Street, Fairfax, Virginia.

Space for Rear Projection. In designing for rear projection, one of the problems the architect faces is the allowance of the correct amount of space for the location of the projection equipment. Figure 8a shows a projector located at a 1 W throw distance and indicates the maximum bend angle for seat A as over 75. This is unsatisfactory for this seat; the allowable bend angle is established by the screen characteristics, and at present, the maximum bend angle is 60. Figure 8b shows a 2 W throw distance and a maximum bend angle at seat A of about 60, which is satisfactory. Figure 8c shows a total depth of rear projection area as 1 W, but by using a mirror, it still permits a 2 W throw distance and a 60° bend angle.

Mirrors Reduce Light. The use of mirrors, however, has its drawback in that about a 10 percent loss of image brightness occurs. One must also be careful of reflections of ambient light of other projectors or classroom light passing through other screens and affecting either the mirror or the screen. This can be combatted by locating black drapes to mask the projectors from this stray light.

Some General Rules. A few general rules are helpful in locating projectors and establishing space for rear projection equipment:

- The larger the screen, the longer the throw distance.
- Conversely, the smaller the screen, the shorter the throw distance.
- Mirrors may be used to fold the projection beam for space saving with smaller screens or with projectors with high lumen output on larger screens.
- For initial schematic design a 2 W depth behind all the screens should be allocated for the rear projection area.
- The use of extra closeup lenses decreases the viewing area, and may result in some distortion around the edge of projected images.

COLLEGE AND UNIVERSITY FACILITIES

Large-Group Facilities

Fig. 8

The Viewing Area *Viewing Area Not Critical in Most Classrooms.* Before projected materials were introduced, the objects to be viewed in the usual schoolroom were the instructor, the chalkboards, and sometimes maps and charts. The instructor was free to move about the room, and the other objects of visual attention were usually distributed over several wall areas. All of them received their illumination by the general lighting of the room itself. With no fixed area of attention, sightlines and viewing were not critical as long as the general lighting was adequate.

Projected Images Restrict Viewing Area. For the effective use of visual aids, however, the requirements for good viewing are much more demanding. The projected image necessarily occupies a fixed position, and, except on the TV receiver, is in a flat plane. Whereas a three-dimensional object may well be viewed from the side, a flat picture can be seen intelligibly only within the limits of a "cone of view." To see the image properly, the viewer must be within the limits of this cone, and neither too near the image nor too far from it. The area defined by these limits is referred to as the viewing area. Its importance in the planning of spaces for image viewing is fundamental, whether the space be a small informal conference area or a large formal lecture hall.

Shape of the Viewing Area. The shape of the viewing area, then, is approximately as shown. Its size is always based on the size of the image to be viewed. The human eye comprehends detail only within a limited cone angle (about $2\frac{1}{2}$ min of arc), and the length of chord subtending this arc, e.g. the image width, varies with its distance from the observer. Thus an object 20 ft away and 6 ft long appears the same as a similar object 10 ft away and 3 ft long. The size of the viewing area is determined by three dimensions, as shown in Fig. 9.

- The minimum distance (1), which is the distance from the nearest part of the image to the eye of the closest viewer

- The maximum distance (2), which is the

Fig. 9

distance from the furthestmost part of the image to the most distant viewer

- The maximum viewing angle (3), which is the angle between the projection axis and the line of sight of a person located as far from this axis as he can be and still see all image detail in proper brilliance

Two Ways of Establishing the Viewing Angle. Whether the apex of the maximum viewing angle should be located at the screen or at some other point on the projection axis is a moot point. There is some disagreement among authorities, too, as to how it should govern the side limits of the viewing area. Some prefer the use of the "edge angle," while others use the angle at the center of the screen. By either approach, the limits defined are essentially similar. In this study, an edge angle of 40° has been used in laying out viewing areas for rear projection, since it is felt this best represents average screen characteristics. With front projection, the use of the "center angle" is probably more common practice, and its values range from 20° to possibly as high as 50° . The maximum value of the angle used in determining the viewing area for receiver TV is 45° .

Minimum and Maximum TV Viewing Distances

Size of TV tube	Min viewing distance, 4 W	Max viewing distance, 12 W
17 in.	4 ft-11 in.	14 ft-9 in.
19 in.	5 ft-1 in.	15 ft-2 in.
21 in.	6 ft-4 in.	19 ft-0 in.
23 in.	6 ft-6 in.	19 ft-4 in.
24 in.	7 ft-5 in.	21 ft-5 in.
27 in.	9 ft-8 in.	24 ft-5 in.

Defining Minimum and Maximum Viewing Distances. Practical minimum and maximum distances are both expressed as multiples of the image width (W). They vary both with the medium being used and with the type and quality of material being projected, and may be affected also, in some degree, by personal preferences. They have not yet been precisely determined by scientific methods, and it is doubtful that such data would have much practical value anyway. The generally accepted values, resulting from numerous studies, are these: (See Fig. 10.)

	Film, slides and projected TV	TV receivers
Minimum distance	2 W	4 W
Maximum distance	6 to 10 W	12 W

Relation of Screen Size and Viewing Area. Since the size of the viewing area is a function of the image width, it follows that the proper

screen size for any given space will be determined by the number of viewers intended. Conversely, a given type and size of screen automatically establishes the size of the viewing area, and consequently the size of audience that can be properly accommodated. The viewing area is the pattern which determines the seating arrangement in any learning space where projected images are to be used, and in the larger spaces, at least, it also influences the shape of the room. (Fig. 11.)

Planning the Projection System *Steps in Design.* Whether front or rear projection is to be used, the design of the projection system itself involves determining:

1. The size of viewing area required
2. The appropriate screen size
3. The proper type of screen
4. The appropriate projector(s)—the required lumen output, focal length and location
5. The maximum permissible level of ambient lighting on the screen.

Trial and Error at First. The desired audience size is usually predetermined. In some cases, the size of the viewing area, too, may be established by existing conditions. Otherwise, its size and shape should be tentatively

Fig. 10

approximated in accord with the principles already discussed. Because of the relationship between its dimensions and the width of screen to be used, the inexperienced designer necessarily proceeds by trial and error until he arrives at a satisfactory arrangement accommodating the specified audience in proper relationship with the screen. Sometimes, the problem may be reversed, requiring a determination of the optimum audience and seating arrangement for projection equipment already at hand.

Standards Professional standards accepted by the Society of Motion Picture and Television Engineers have been developed for viewing front and rear projected images. These standards provide excellent images. However, for the purpose of economy in classroom use of projected media, it is felt that some standards based on the poorest seat in the room can be lowered, particularly for gross images. The following resumé of standards indicates by asterisk (*) those that are less than the professional standards.

Screen Brightness

Motion pictures:

- 5 ft L—Minimum* (gross images)
- 10 ft L—Satisfactory
- 15 ft L—Excellent
- 20 ft L—Maximum (flicker threshold for some observers)

Slides:

- 2.5 ft L—Minimum* (gross images)
- 5 ft L—Minimum for slides with detail
- 10 ft L—Satisfactory
- 20 ft L—Excellent

COLLEGE AND UNIVERSITY FACILITIES

Large-Group Facilities

Fig. 11 Viewing areas for two- and three-screen projection.

Projected TV:

- 2 ft L—Minimum* (gross images)
- 20 ft L—Maximum (flicker threshold for some observers)

TV monitors:

100 lumens per square foot

Brightness Ratio

- 2:1—Excellent
- 3:1—Very good
- 10:1—Acceptable* under some conditions

Contrast Ratio

- 100:1—Pictorial scenes
- 25:1—Good legibility of printed characters
- 5:1—White letters on black background
- 30:1—Minimum* contrast ratio for poorest seat dictated by higher levels of classroom light and many types of projected materials

Contrast ratio is determined in part by non-image brightness which, in turn, is related to screen reflectance and room ambient light. Therefore, controlling the amount of ambient light reaching the screen is important. For large screen installations, if the amount of ambient light occurring at the screen is held to 1–2 ft C, the contrast ratio will normally be adequate.

Writing Surface Lighting Levels Ideally, an average ratio of 1:1 between writing surface brightness and screen brightness should be maintained, while not spilling excessive ambient light on the screens. Since screen brightness varies for each seat in the viewing area, the average condition of brightness for each broad class of projected material should be approximately satisfied. For a medium to large size room, three lighting levels would be in the range of:

- 5–10 ft C—Projected TV and films
- 10–20 ft C—Slides
- 30 + ft C—Other class activities

and medium group situations. These "media modules" can be of several types:

- A fixed cabinet with self-contained equipment, rear projection screen, and several additional "swing-out" display surfaces.

- Same as above, only the entire media module would be mobile.

- A basic fixed cabinet with rear projection screen and "swing-out" display surfaces. Projection equipment would be mounted on mobile carts which would roll into the cabinet and which would permit the interchanging of projectors.

- Same as above with both the basic cabinet and the equipment carts mobile.

- Any of the above, but with a cabinet and rear projection screen sized to accommodate two rear projected images side-by-side.

Media modules have several attractive features. They can be fabricated in a shop and installed in existing classrooms with little disruption of normal class meetings; in this way, media modules can quickly and inexpensively convert existing facilities for uses of media. Both in building new facilities and remodelling old, the media module is a rela-

tively inexpensive answer initially, which also readily adapts to new and improved equipment. Mobile units can be designed for flexible spaces where the regrouping of students frequently is an important functional requirement; fixed installations of media might not be feasible in such circumstances. As illustrated in this study, media modules can be used to increase the utilization of facilities such as dining rooms and gymnasiums by also allowing them to be used for instruction.

The accompanying figure (Fig. 12) shows one type of media module which was designed and built. The basic cabinet with screen and display surfaces could be either fixed or mobile. Various types of projectors can be mounted in the cart, which is rolled into position for projection on the rear projection screen. Remote controls operate the equipment and the rear screen is of the flexible type. This media module has a screen surface 32 in. square and the entire unit stands 6 ft–8 in. high. Naturally, these dimensions will vary from module to module.

Furniture Planning Furniture an Integral Part of the Design Process. For effective uses of media in education, the manner in which classrooms, seminar rooms, independent study facilities, and other learning spaces are furnished is an important design decision. Unfortunately, too often the selection and purchase of furniture are left until too late in the planning process when energies, funds, and professional services have been expended. Furniture, as part of the learning environment, should be considered an integral part of any space in which media are to be employed; its selection should be based on careful study and professional advice early in planning. Most importantly, functional, aesthetic, and economic criteria should be established during the programming stages when the functional requirements of the spaces are spelled out.

Fixed Seating—Continuous Counters with Fixed Seats. Many types of seating for learning spaces are available, but their individual appropriateness varies from space to space. Of the three basic types of seating (fixed, movable, and combined) fixed has had the advantage of guaranteeing that, once properly positioned, every student will always be in the proper relationship to screens and other display surfaces. Of the various types of fixed seating, the continuous counter with individual fixed chairs provides a desirable surface for writing and for holding references. This is particularly important in secondary and higher education where the learning process may require extensive use of various types of materials and resources during a class. Also,

Fig. 12

Media Module This study led to the design and development of a self-contained media cabinet which might be used in many types of small

COLLEGE AND UNIVERSITY FACILITIES

Large-Group Facilities

a continuous counter works well when portable, audiovisual equipment, small demonstrations, or various forms of teaching machines are to be used by students at their seats, or when student response systems, requiring the use of a response panel at each station, are to be installed initially or planned for later installation. This type of seating does require more floor area per unit than most other types of fixed seating, but this may be compensated for by the provision of cross aisles between each row of seating, allowing students to move freely to and from their seats.

Fixed Seating—Theater Types. There are many so-called "theater-type" of fixed seating employing a seat with a folding or lifting individual writing surface. Unfortunately, many of the tablet arms provided with this type of seating have the disadvantage of being too small to accommodate writing and reference materials. Lately, some improvements in seating have resulted in folding tablet arms that are adequate in size. Generally, fixed seating of this kind requires less floor area than the continuous counters, but student access to his individual seat is more limited. Also, the necessary moving parts to raise and lower the tablet arms can create maintenance and upkeep problems. Installation of response devices and outlets for equipment can be handled in seating with movable tablet arms, but this again introduces maintenance problems.

Movable Seating. Movable seating also introduces a variety of alternatives, and again the provision of an adequate writing surface is extremely important. In rooms where regrouping of students is important, separate

table units or seat-table units that are modular to allow conference and discussion groupings are desirable. Movable seating mitigates against the use of any individual student instructional device requiring wiring, such as response systems, portable recorders or projectors, and power-operated teaching machines. Particularly with movable seating, seating should be scaled and designed with the age and character of the students in mind.

Combined Seating. Combined seating is basically of one type—continuous counter with loose seats. This type has the advantages of flexibility, accommodation to many body postures, and reduced cost over the continuous counter with fixed seats. However, the interpretation of building codes may prohibit continental seating in large rooms. The accompanying diagram (Fig. 13) shows several of the fixed and combined types of seating that are available, together with the average size of writing surfaces and the floor area required.

A Mix of Seating Is Often the Answer. In many instances, several types of seating in one space may best meet functional needs. For instance, loose tables and chairs on a flat floor area at the front of a large teaching room can be used for case studies, moot courts, and other instructional methods, while the remainder of the seating is fixed on a sloped or stepped floor. Also, in rooms requiring raised seating, rows of seating may alternate between riser-mounted and floor-mounted types. Particularly in medium group spaces, various types of loose seating may meet the varying requirements dictated by multi-age, multi-class, and nongraded approaches to learning.

Importance of Good Sight Lines from All Seats. Certainly in rooms where projected media are to be used extensively, good sight lines from all seats to all screens are important. Where 40 or more students are involved, this will generally require stepped or sloped floors. However, steep slopes such as seen for years in college lecture halls or amphitheaters are not always necessary. These slopes have usually been dictated by a functional requirement that every student be able to see the top of a demonstration table at the front of the room. Rather than thus increasing the volume of the room, and the cost of the room, electronic means of magnification should be employed which shifts the functional requirement from viewing a demonstration table to the more easily accommodated viewing of screens. By offsetting the rows of seating, and by using platforms containing two rows of seating each, the volume of the room can be reduced without impairing the viewing of screens and information display surfaces.

Investigate the Advantages of Continental Seating. In laying out seating in the larger rooms, continental seating, which allows cross aisles between the rows of seats, should be explored. This arrangement can move aisles outside the viewing area, can allow longer rows of seats, and can permit students to move to and from their seats without disturbing other students. The square footage per seating unit based on the total room area may not be much greater than that for more conventional arrangements. Each such solution must be judged in accordance with the applicable building code.

Theater-Arts-Laboratory Teaching Station

THEATER-ARTS-LABORATORY
TEACHING STATION

There are many types of space facility which may be employed in the Theater-Arts program. The Theater-Arts-Laboratory Teaching Station is primarily a classroom which is designed for, and specifically allocated to, the teaching of theater-arts subjects. It is presumed that this room will probably be assigned to a single teacher, or to a small group of teachers, employed in a team-teaching concept. With only slight expansion, however, it might serve in some instances as a very comfortable and pleasant place for public performances. It is not designed primarily as a replacement for a conventional school auditorium. Its existence, however, will emphasize the fact that the well-appointed auditorium is not essential for the successful pursuance of a theater-arts program. Under ideal circumstances, such a facility is employed on a day-to-day basis by the teacher in the normal progress of instruction, and therefore may be considered a supplement to the auditorium employed for the larger public performances. In addition to the normal daily class functions, it is entirely appropriate to employ the teaching station, on occasion, for public presentation of material adapted to this space, if the seating will accommodate a small invited, or even paying audience.

Although some dimensional data are provided, it should be remembered that they represent only a suggested treatment and that, in specific instances, a room might change its shape perceptibly and be increased or decreased in size. The basic concept of this room implies that its primary function is that of a classroom, and a continual enlargement of this facility approaching a small auditorium would be undesirable. The term "teaching station" is employed rather than "little" or "studio theater" in an attempt to emphasize its classroom function.

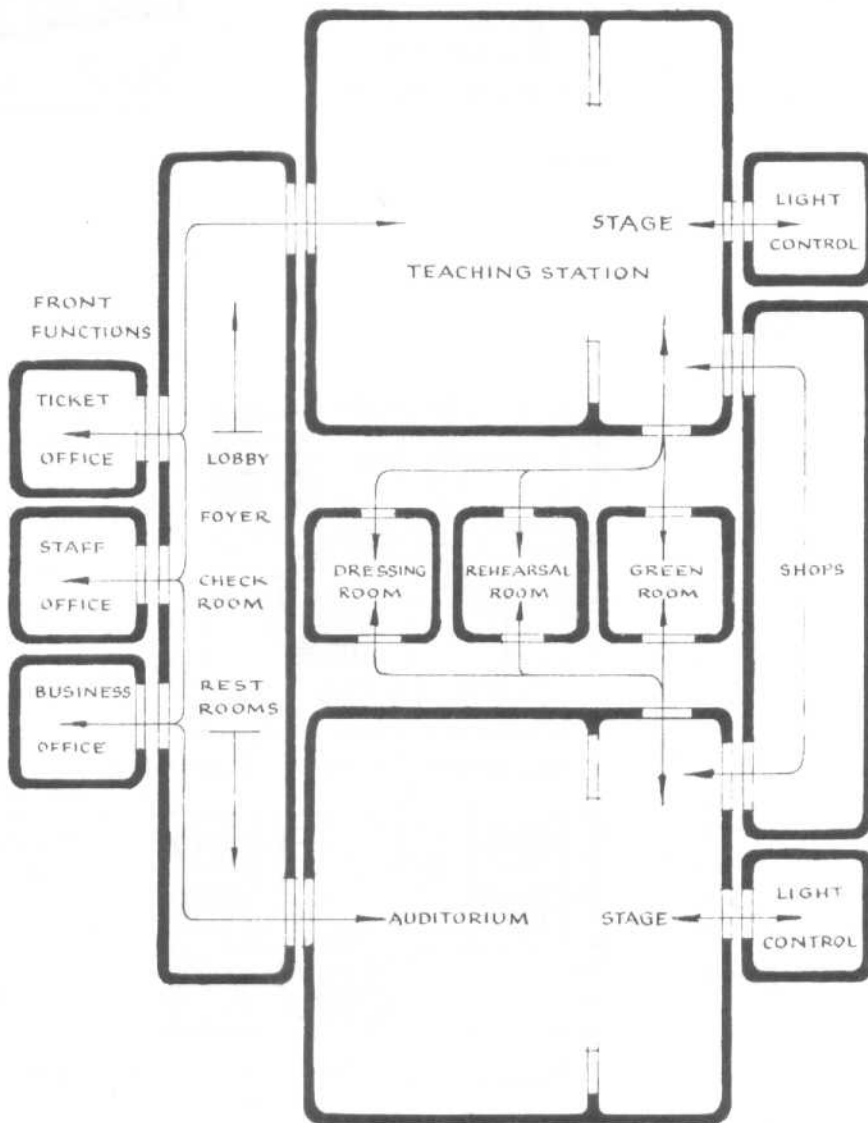

Separate Service Facilities

If the school has separate auditorium facilities, it is recommended that the teaching station be nearby in order that some of the service areas might be employed by both of these theater units. As an example—it would be possible for the teaching station and the auditorium to use the

same dressing rooms, the same lobby space, the same ticket offices, the same rest rooms, the same shop area, and some of the same storage area (see Fig. 1). Although it is true that on occasion both of these producing units might be in performance simultaneously, it is not probable that this would occur frequently enough to warrant complete duplication of all these service areas. However, such support space is absolutely essential, and, if it is not provided in connection with some other function of the building, it will be necessary to plan it in connection with the teaching station. In the description which follows, it will be apparent that there are a number of advantages to having the teaching station accessible from four sides. The dimensional data suggest the possibility, but do not demand that the teaching station

occupy space equivalent in size and shape to two standard classrooms. The recommended plan includes space for normal classroom function, space for arena-type presentation, space for proscenium and thrust stage presentations, and allows all of this space to be converted to other multiple-theater purposes.

The area designated as the teaching station divides roughly into three parts (see Fig. 2). Part one: some fixed seating on an inclined floor accommodating about 30 students, with chairs equipped with movable tablet arms. Within some individual teaching practices the area might be preferred with a flat floor with movable chairs. Part two: an elevated stage, presumably at the opposite end from the fixed seating just described, and with the usual physical and electrical

Architecture for the Educational Theatre, H. W. Robinson, 1970. Reprinted by permission. Copyright © 1970 by University of Oregon.

Fig. 1 Functional and space relationships of auditorium to teaching station. It is highly desirable, as the text indicates, to have both a stage-auditorium and a teaching station in an efficient academic theater plant. If both are provided, it is not necessary to duplicate all of the support functions; avoiding unnecessary duplication will save space and construction costs. This diagram illustrates the desirable functional and positional relationships between the two complementary theater forms.

COLLEGE AND UNIVERSITY FACILITIES

Theater-Arts-Laboratory Teaching Station

equipment. When employed as a proscenium stage, there would be space for seating approximately 80 in the fixed seating described combined with the temporary seating in the space next described. Part three: a flat floor area between part one and part two for rehearsal, demonstration and arena staging, a playing area of at least 14 by 18 ft, and with the usual lighting and mechanical equipment. When this area is employed for arena staging, and all other areas adapted to seating, it can accommodate approximately 140. The minimum width of this room is 24 ft; widths up to 36 ft would prove additionally desirable. The total length of the room, if the areas described are laid end-to-end, is about 70 ft.

If the fixed seating plan is employed for some 30 to 50 seats, and if they are on a raked (inclined) or terraced floor, it is recommended that there be at least a 5-in differential in the height of the rows. Back-to-back spacing of 36 in is recommended for rows, and 20–22 in for individual seat widths. Other seating to be provided should be of padded metal folding chairs with arm rests. Linkable chairs have some advantages in terms of ease of movement, for regrouping, and for cleaning.

The center area of the room is recommended for general demonstration, classroom space, and as an arena playing area for productions to be viewed from four sides. It is suggested that the recessed space might be twenty-one to twenty-four inches below that of the surrounding areas, including the service halls. This provides a depressed area for the arena stage with some seating at that level, with other raised seating on all sides, and it also allows for the elevated proscenium and thrust stage to be above the central floor area. Although the raised stage at the end of the room may be employed as a proscenium stage, it should not be thought of as that exclusively. Its design lends itself to other, flexible treatment. There is no fixed proscenium—the bounding edges of the opening are established by movable sections of wall or by a simple curtain framing. This stage space should be the full width of the room at that end, and should be at least 14 ft deep. Although more-than-usual classroom height is desirable over the stage area, it is not necessary to provide the usual stage house or fly space. It is suggested that two levels (each 3 ft deep) running the full width of the stage be provided in front of the fixed platform area with one-third stage height differential for each, namely 7 or 8 in. These levels can be created by separate, collapsible, or nesting boxes and reemployed as terraced seating spaces for the arena concept, or as variable forestage space as suggested by the accompanying diagrams (see Fig. 4).

A projection room may be provided at the end of the room opposite that of the fixed stage,

to serve as a sound room and a listening room, as well as to accommodate projection equipment.

The ceiling of this room should be approximately 14 ft above the stage level, and should provide, in addition to standard room lighting, other arrangements for the hanging of special stage lighting instruments and other hanging units. These supporting members can be exposed or concealed above a false ceiling. Lighting control may be located either in the offstage area on the fixed stage floor or in the projection room described above.

A walkway at least 42 in wide should be provided on the two long sides of the room which connect the stage level at one end with the entrance level at the opposite end. For classroom use, these levels will be employed as display and work areas at low table height. When the room is employed for arena staging, they serve as elevated rows of seating on the two sides. For end staging, they serve as additional side stages or for walkways approaching the stage for entrance, tableau, or processional purposes. If slightly en-

larged, the space beneath these walkways may be employed for storage for seating or other theatrical equipment.

No attempt will be made here to specify a minimum of equipment for this teaching station, but it is obvious that it must have the usual complement of front traveler, cyclorama, switchboard, and lighting equipment.

Although it is not planned that all three of these areas will be used simultaneously in a classroom teaching station, it is possible to have on stage the fixed stage scenic, lighting, and property elements to be used for a public presentation or for the use of another class while the teacher lectures or conducts a demonstration in the central area without having to clear this material. In the same way a set-up can remain in the arena section and the teacher will still have a lecture area and a drill or rehearsal area unencumbered.

The essential features of this classroom teaching station are designed specifically to serve the purposes of theater instruction, but if, in scheduling, it appears that the room will not be in contin-

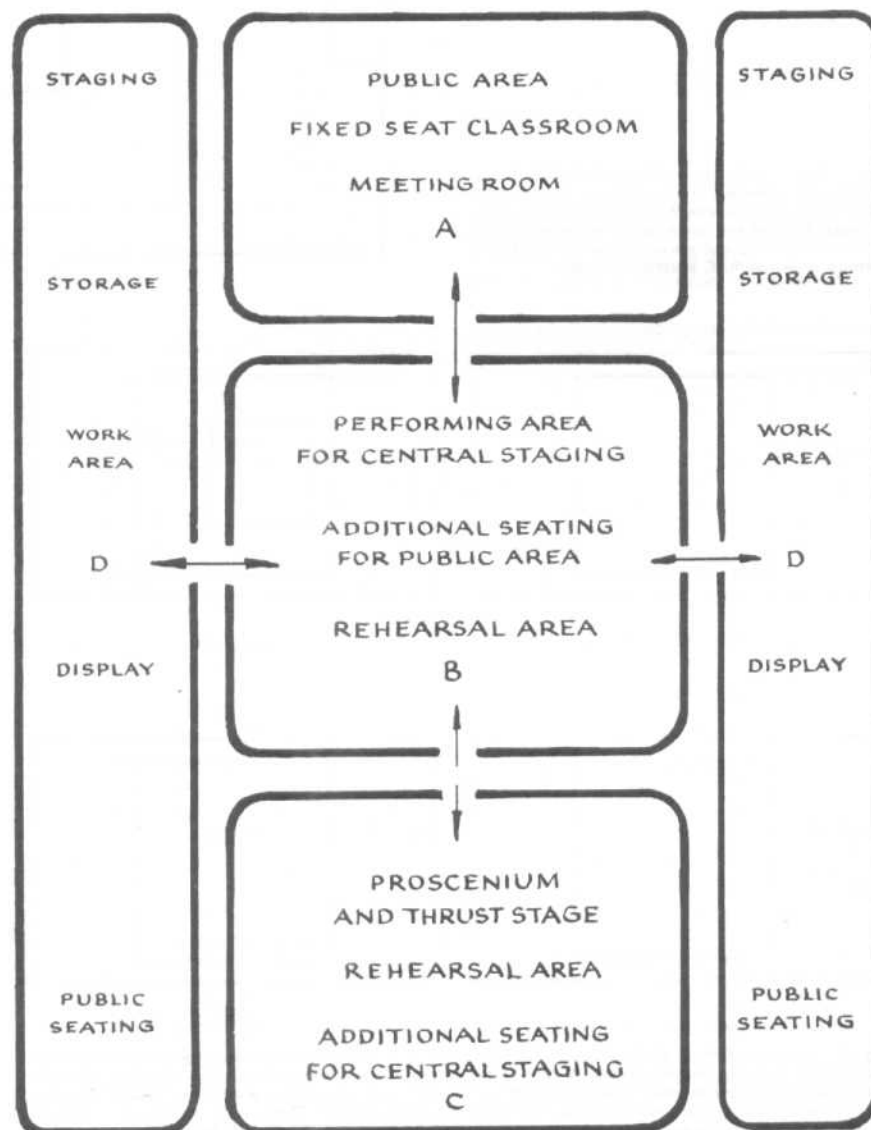

Fig. 2 The teaching station. The teaching station provides space for all theater functions such as work areas, rehearsal areas, classroom, and public seating for all three basic theater forms: thrust, arena, and proscenium. It is multifunctional in terms of space, but can seldom accommodate more than one function at one time. The basic concept calls for three major tandem spaces, A, B, C, and two flanking spaces, D; all are multifunctional. The dimensions of these spaces are optional (see text). This diagram shows the interrelationship of the spaces and their function, and introduces the plan presented in Fig. 3.

COLLEGE AND UNIVERSITY FACILITIES

Theater-Arts-Laboratory Teaching Station

ual use, it may be employed quite effectively in the true multiple-function sense. Although specifically designed for theater purposes, it has not lost its usefulness as a general classroom regardless of subject matter. It has a raised stage for any type of classroom performance, a large flat floor space for activities such as dance, and may even be used as a small lecture hall.

Fig. 3 Teaching station: section and plan. A. Fixed seating; B. potential arena staging; C. elevated stage, no fixed proscenium; D. elevated walkways on each side of the room serve as work tables and arena seating and provide chair and platform storage underneath; E. projection room.

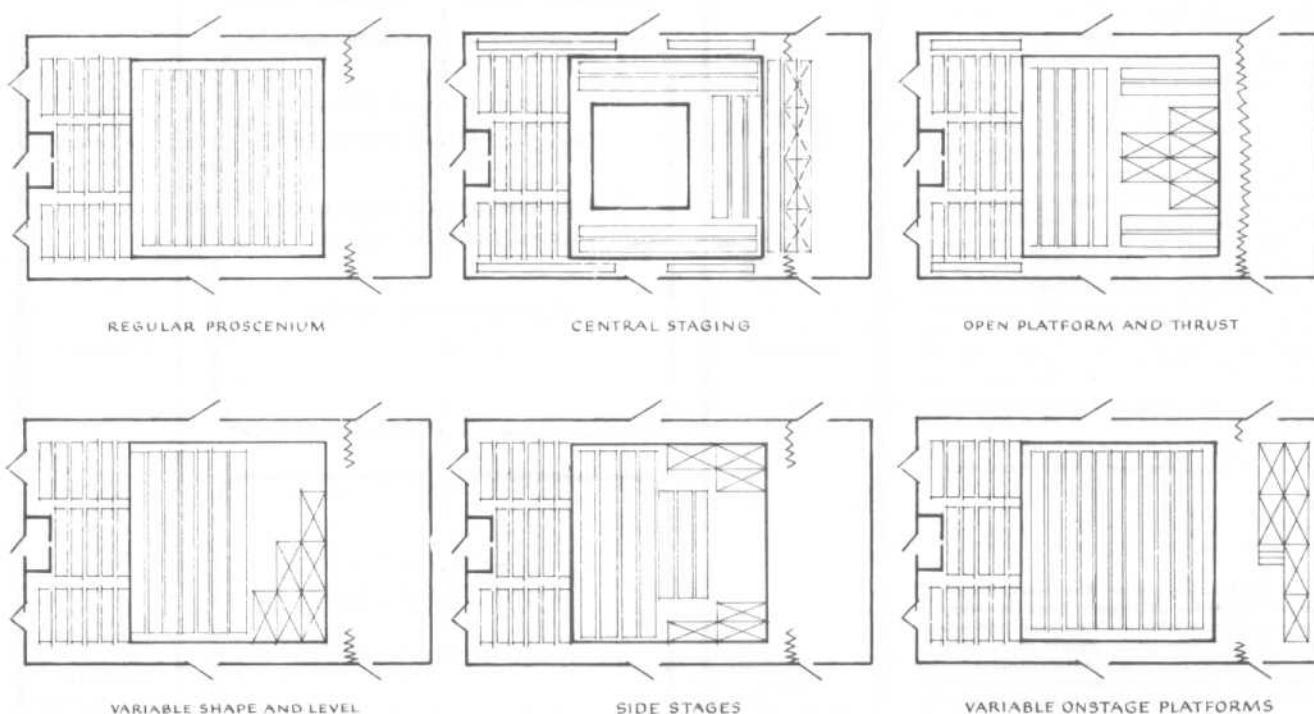

Fig. 4 Teaching station: platform and seating alternatives. The standard teaching station is readily convertible to many staging forms. A few of the alternates are suggested in this diagram. Portable platforms of standard modular dimension such as 3 by 6 ft may be used as a base for audience seating on varying levels, or stacked to change the height of playing levels. These units are stored, when not in use, under the forestage and under the elevated walkways at each side of the room. Stair units of compatible height increase the flexibility of the system. Infinite variety is available with the exercise of imagination (note that the fixed seating remains the same for each alternate).

Programs and Programming

By JAMES A. PADDOCK, Dober, Paddock,
Upton and Associates, Inc.

PROGRAMS AND PROGRAMMING

Until recent years large building projects were launched by nothing more than a conversation between an individual client and the architect of his personal choice with, perhaps, some reference to a historical precedent with which both were familiar. The resulting inconvenient planning and lack of facilities and equipment in buildings of all types appeared to be of little consequence. Labor was cheap and plentiful; space was at a discount; client and architect could afford to waste space.

Recently several changes in society have affected the way in which new building is brought into being: the autocratic statesman, industrialist, and educator has been supplanted by the building committee; the personal fortune has been replaced by the finance committee and program budgeting; and building requirements have become vastly more exacting in response to the technological revolution in government, industry, and education. At the same time, the private conversation and occasional letter between client and architect has given way to a wordy document by which a many-headed client instructs an architectural organization and many specialists in building design and construction. This document is sometimes called "user requirements" or "building specifications"; more frequently it is known as the "program." Generally, programs are of two types, serving different purposes.

Master Plan Program

The program for the master plan is concerned with large-scale development to be accomplished in several phases over many years. It deals in building space to the nearest thousand square foot and required site area in acres. The master plan program may be used to determine the area of land to be acquired for the new development, to assess the adequacy of an existing site and utilities to accommodate future requirements, to estimate development costs, and to raise funds.

Building Program

The building program is concerned with detailed space descriptions for immediate new construction and deals in building space to the nearest hundred square foot. The detailed building program may be used as the basis for the architect's design. It also may be used to conduct an architectural competition for the selection of an architect, to estimate construction costs, to estimate furniture and equipment requirements, and to raise funds.

A program may be concerned with the expansion of existing physical facilities to accommodate a growing organization, or with the development of new facilities on a site not yet selected for an organization in process of formation. In either case, the program is a set of instructions and criteria derived from consideration of many factors, including at least the following:

1. *Policy.* The organization's goals and objectives for future growth and change. In an educational institution this would be known as the academic plan.

2. *Projection.* Anticipation of numbers and characteristics of people to be accommodated at some point in the future or at some selected level of activity, population, or enrollment.

3. *Criteria.* Space planning standards for

people and equipment and other factual requirements which must be met.

4. *Spatial relationship.* The desired relationship among individuals, groups, and the equipment they use; their relationship to visitors,

TABLE 1 Sample of Typical Program Sheet

Audio visual and TV	
Existing operations	Function: The Audio Visual and Television Centers, although headquartered together, are independent operations. The Audio Visual Center is financed by the College; the Television Center is financed by the Education Department. The Audio Visual Center conducts courses required of all Education majors and prepares and distributes all films and other audio visual aids, distributes all television tapes prepared by the Television Center, and provides projection and other technical personnel to all departments. The Television Center prepares television tapes for teaching purposes. Facilities: Existing space is cramped and inappropriate to the function housed. (The television repair center is in a mechanical equipment room containing steam-operated hot-water boiler and reaches 100° during the summer.)
Anticipated changes	Function: The trend toward interdisciplinary operations will bring the two centers closer together. Facilities: Although the Audio Visual and Television Centers will each require their own office and studio facilities, technical and support spaces may be shared.
Location criteria	Located adjacent to a space easily vacated to accommodate unforeseen future expansion.
Planning assumptions	Separate graphic arts and photography facilities will be provided for the Audio Visual Center and College Relations and Publications.

TABLE 3 Sample of Detailed Building Program Space Description

Area Number:	MM-11
Name of Space:	Biology/chemistry preparation room
Number:	One
Floor Area:	180 sq ft
User:	Faculty, lab technician
Purpose:	Preparation and setting up of movable demonstration bench, storage of chemicals and apparatus, storage of bench
Ceiling Height:	No special requirements
Lighting Requirements:	No special requirements
Heating, Ventilating, Air Conditioning, Exhaust:	Fume hood
Suggested Materials for Floors Walls:	Acid resistant floor and base
Ceiling:	
Doors:	If direct access is provided to hall, then door to hall to be solid core or equivalent, gasketed; window with sliding panel, door width to allow passage of movable bench
Equipment and Furniture:	1. Chemical bench 12 ft long with sink, hot and cold water, gas, vacuum, and air, chemical resistant stop, cupboards and drawer under; reagent shelf, acid drain 2. Storage cabinets and shelving 3. Fume hood 4. Electric wall clock 5. Steel chalkboard, 4 × 3 ft 6. Pegboard, 4 × 3 ft for drying glassware 7. Stool
Special Utility Requirements:	Plugmold on wall above bench
Spatial Relationships:	Adjacent to hall at stage level and to service access

the public, and others outside the immediate organization; and the flow of information, supplies, and material.

5. *Constraints.* Limitations of budget, time, area of site, zoning restrictions and availability of special equipment.

Programming

The process by which the program is produced is called programming. This may be done by

the client (the people who are going to use the building), the architect, or a consultant. In any case, the process is essentially the same and consists of the following steps.

1. *Existing data.* Assembly and review of all existing documents concerning policy decisions, enrollment projections, corporate plans, and other papers that describe the present and future structure of the organization.

2. *Planning committee.* Appointment of a planning committee to review the programming

work as it proceeds, to resolve possible conflicts over such matters as the allocation of space or other resources among competing divisions, and to approve the completed program document. The committee should include a representative of each functional area within the organization. Most of these functional areas can be identified prior to the beginning of the programming process by reference to organization charts and telephone directories and through consultation with administrators. The size and, consequently, the number of functional areas specified depend largely on the level of detail to which the programming is expected to go. For example, all administrative functions might be subsumed under an Office of the Vice President for Administration. If more detail is required, subdivisions might be made to establish separate offices for fiscal planning, personnel, buildings and grounds, etc.

3. *Interviews.* Interviewing individuals and groups representing each functional area within the organization. The purpose of these interviews is to ask the individual, Who are you, what do you do, how do you do it, with whom, and in what kind of space? Ideally, these discussions should almost never touch on the question of how much space is needed. The programmer should know from the space inventory how much space exists, if any; and he will be able to observe overcrowding or gross under-utilization. The person using the space is the expert regarding how it is used. The programmer is an expert in translating need into square feet. The success of the discussions depends upon each party's ability to stay within his own area of expertise.

4. *Draft program.* Following the interviews, the programmer writes a detailed sheet for each functional area (see Tables 1 to 3). The draft program sheet will include the programmer's analysis of the spaces required and their sizes. The sheet is then sent to the person interviewed. Review and further discussion take place as required until he is satisfied that the program sheet represents his explicit understanding of need.

Fig. 1 Program process outline.

COLLEGE AND UNIVERSITY FACILITIES

Programs and Programming

5. *Committee review.* The planning committee meets to review the draft program sheets. The committee must judge individual space requests in the context of the whole organization. It must ensure that requests are not redundant but complementary and that no intercasts have been ignored.

6. *Estimate of building size and cost.* The program consultant totals the net square foot space, requests, and estimates the building area needed in gross square feet. This is done by applying a "net-to-gross" multiplier to allow for circulation space, washrooms, mechanical equipment areas, and wall thicknesses. Typical multipliers are 1.66 for offices, 1.35 for undergraduate libraries, and 1.25 for auditoria. The total gross square footage is now used to make

an approximate estimate of construction cost. Other costs such as furniture, equipment, site works and professional fees may be estimated in order to arrive at a total development cost.

7. *Final decision and review.* The committee now has a list of carefully considered statements concerning the amount and type of space required by each functional area based on specified assumptions concerning its responsibilities, and an approximate estimate of the cost of developing a building or buildings to accommodate the programmed spaces. It is highly likely that the total demands exceed the organization's resources. The task now is to decide how much space should be allotted for each purpose. The planning committee may

resolve the conflict, or the president of the organization and some representative group of advisers may make the final decisions concerning allocations of space or development funds.

The process outlined above reduces a vast amount of data to a reasonable set of statements concerning any one of which there should be little or no argument, and so the decision-making process should be comparatively easy. When the decisions have been made, the organization will have clarified its goals and established a reasonably firm basis for physical planning and architectural design. Figure 1 illustrates the programming process as it might apply to an educational institution.

GENERAL OBSERVATIONS

Whenever it is proposed to build a museum—whether large or small—there is usually one preliminary matter to be settled: the choice of a site. Where several possibilities are available, the drawbacks and advantages of each must be carefully weighed.

Should the site be central, or on the outskirts of the town? This appears to be the most usual dilemma. Until 20 or 30 years ago there was a preference for the center of a town, with its better transport facilities. But as the use and speed of public and private transport have gradually increased and it has become easier to get from one point to another, it has been realized that the convenience of a central situation for a museum is outweighed by the many and substantial advantages of a less central position. These include a greater choice and easier acquisition of land (at lower cost), less fatigue from the noise of traffic—a growing and already very real problem—and an atmosphere less laden with dust and with gases which when not poisonous are, to say the least, unpleasant.

A museum should always be readily accessible from all parts of the town by public transport and, if possible, be within walking distance as well, and must be within easy reach of schools, colleges, university, and libraries. As a matter of fact, all these institutions have similar problems and stand equally in need of topographical coordination; it would be advisable to take this into account at the town-planning stage, rather than deal with each case separately, as it arises, a method which may involve the sacrifice or neglect of many desiderata.

Museums tend nowadays to be regarded more and more as "cultural centers." It must therefore be remembered that as such they are visited not only by students but by people with different backgrounds who, if a museum is near enough and easy to reach, may come to it, even with little time to spare, in search of instructive recreation.

Though there is still a prejudice against the building of museums in parks or gardens—on the plea that this makes them more difficult to reach and disturbs the tranquillity of such places—these are becoming very popular as the sites of new museums. They offer considerable advantages—a wider choice of detached positions, thus reducing the risk of fire; a relative degree of protection from dust, noise, vibrations, exhaust gases from motor engines or factories, smoke from the chimneys of houses and from municipal heating plants, the sulphur content of which is always harmful to works of art.

A belt of trees surrounding the museum building serves as an effective natural filter for dust and for the chemical discharges that pollute the air of a modern industrial town; it also helps to stabilize the humidity of the atmosphere, to which paintings and period furniture are often sensitive. It is said that large trees, if unduly close to the building, cut off or deflect the light and thus diminish or alter its effect

on color; but this disadvantage would appear to be unimportant, or in any case easy to overcome.

The surrounding land may offer space for an annex, built at a suitable distance from the museum itself, to house various types of equipment and services (heating and electricity, repair shop, garage, etc.), or the stores required for them (wood, textile materials, fuel oils, etc.), which it would be unsafe or, for some reason, inconvenient to stock in the main building.

Moreover, space will always be available—at least in theory—for future expansion, either by enlargement of the original building or by the construction of connected annexes; this is particularly important if the first project has to be restricted in scale for reasons which, though unavoidable, are likely to be transitory.

The beauty of a museum is considerably enhanced if it is surrounded by a garden which, if the local climate is propitious, can be used to advantage for the display of certain types of exhibit, such as ancient or modern sculpture, archaeological or architectural fragments, etc.

Part of the surrounding grounds may also provide space for a car park.

The planning of a museum is an outstanding example of the need not only for preliminary and specific agreements but for close and uninterrupted collaboration between the architect and his employer.

There is no such thing as a museum planned in the abstract, suitable for all cases and circumstances. On the contrary, every case has its own conditions, requirements, characteristics, purposes, and problems, the assessment of which is primarily the task of the museum director. It is for him to provide the architect with an exact description of the result to be aimed at and of the preliminary steps to be taken, and he must be prepared to share in every successive phase of the work—failing which the finished building may fall short in some respects of the many and complex technical and functional demands which a modern museum must satisfy.

Another point to be considered is whether the new building is to house an entirely new museum (whose contents have yet to be assembled) or to afford a permanent home for an existing collection. In the first case we have the advantage of a free approach to the problem and can decide on an ideal form for the museum; but with the attendant drawback of beginning our work in the abstract, on the basis of entirely vague and theoretical assumptions which future developments will probably not confirm. In the second case we must take care not to go to the opposite extreme by designing a building too precisely adapted to the quality and quantity of the works or collections which form the nucleus of the museum; future needs and possibilities of development should always be foreseen and provision made for them.

All this is part of the director's responsibility.

Due regard should also be given to the special character of the new museum—the quality it already possesses and by which it is in future to be distinguished—in relation to its collections. This may, of course, be of several kinds (artistic, archaeological, technical, scientific,

etc.) and respond to various needs (cultural, general or local permanence or interchangeability, uniformity of the exhibits or group display, etc.).

Naturally, every type of collection, every kind of material, every situation has its own general and individual requirements which will considerably influence the structure of the building and the form and size of the exhibition rooms and related services. It is no use attempting to present a series of archaeological or ethnographical exhibits, whose interest is chiefly documentary, in the space and surroundings that would be appropriate to a collection of works of art, paintings, or sculpture of great aesthetic importance, or to apply the same standards to a museum arranged chronologically and one whose exhibits are classified in artistic or scientific categories; nor is it possible to display a collection of small works of art, such as jewelry, small bronzes, medallions, miniatures, etc., in rooms of the size needed for large objects of less meticulous workmanship, which require to be seen as a whole and from a certain distance.

Even a picture gallery cannot be designed in such a way as to serve equally well for the exhibition of old pictures and modern ones: for, apart from the fact that aesthetic considerations recommend different settings for the two groups, it is obvious that a gallery of old paintings is comparatively "stabilized," whereas the appearance of a modern gallery is to some extent "transitory," owing to the greater ease and frequency with which additions, changes, and rearrangements can be made. In the latter case, therefore, not only the architectural features of the building but also its actual construction must be planned with a view to facilitating the rapid displacement and change-over of exhibits. The transport of heavy statues, the adaptation of space and the use of the sources of light in the way and on the scale most appropriate for particular works of art, should be taken into account as well as the possibility either of grouping or of displaying them singly, according to the importance and emphasis to be attributed to them.

A museum must be planned not only in relation to its purpose and to the quality and type of its exhibits, but also with regard to certain economic and social considerations. For instance, if it is to be the only institution in the town which is suitable for a number of cultural purposes (theatrical performances, lectures, concerts, exhibitions, meetings, courses of instruction, etc.) it may be desirable to take account in the initial calculations of the financial resources on which it will be able to rely, the nature of the local population, the trend of development of that population as revealed by statistics, and the proportion of the population which is interested in each of the museum's activities.

In fact, the word "museum" covers a wide range of possibilities, and the architect commissioned to design one must make clear—to himself first of all—not only the specific character of the museum he is to build but the potential subsidiary developments and related purposes which can be sensed and foreseen in addition to the dominant theme.

The future may see substantial changes in

our present conception of museums. If the architect who designs one allows in his plan for easy adaptation to new fashions, new developments, new practical and aesthetic possibilities, his work will be all the sounder and more enduring. A museum is not like an exhibition, to be broken up after a short time and brought together later in an entirely different form. There should be nothing "ephemeral" in its character or appearance, even where the possibility of changes or temporary arrangements is to be contemplated.

These considerations should be borne in mind when the architectural plans for the building are drawn up.

According to a prejudice which, though gradually dying, is still fairly common, a museum building should be imposing in appearance, solemn, and monumental. The worst of it is that this effect is often sought through the adoption of an archaic style of architecture. We are all acquainted with deplorable instances of new buildings constructed in imitation of the antique; they produce a markedly antihistorical impression, just because they were inspired by a false view of history. Another outmoded prejudice is that which demands a "classical" setting for ancient works of art, as though their venerable dignity would suffer and their aesthetic value be diminished if they were placed in modern surroundings.

But though the style of the building should be frankly contemporary and governed by the creative imagination of its designer, architectural interest must not be an end in itself but should be subordinated to the purpose in view. In other words we must not devote our entire effort to designing rooms which will be architecturally pleasing; it is at least equally important that attention be concentrated on the works exhibited, that their *mise en valeur* be ensured and their predominance established. A museum in which the works of art were relegated to the background and used to "complete" a pretentious architectural scheme, could not be regarded as successful; but neither could a museum which went to the other extreme, where the construction was subordinated to cold, mechanically functional considerations so that no spatial relationship could be created between the works of art and other exhibits—a museum with a completely impersonal atmosphere.

The ideal would seem to lie somewhere between these two extremes—the aim being to allow for that sense of proportion which should always be in evidence when a museum is planned, to ensure that the visitor will find there the friendly, welcoming atmosphere, the attractive and convenient features that he enjoys in his own house.

It is the difficult but essential task of the architect, no less than of the director of a museum, to bring the place into conformity with the mentality and customs of every citizen of whatever rank and standard of education. Much will depend on the level of taste of both men, on their human qualities of sympathy and sensibility, which must go hand in hand with their professional abilities and which cannot be prompted or taught.

PLANS FOR SMALL MUSEUMS

The foregoing remarks apply to every new museum, whatever its size. We shall now consider more particularly the principles and characteristics on which the planning and construction of small museums should be based.

By "small museum" we understand any in-

stitution whose program and finances are restricted so that, at least at its inception, the premises built for it will be of limited size, in most cases only one story high.

It is not so easy to determine precisely within what limits the idea of the "little museum" is to be confined; for while it may, at its smallest, consist of one room, it may on the other hand be of an appreciable extent, though still too small to be properly described as a medium-sized or large museum.

For the present purpose it may be assumed that the "small museum" will not consist of more than 10 to 12 medium-sized exhibition rooms (16 × 24 sq ft) in addition to its other services.

A new museum, even on this small scale, cannot function efficiently unless it respects the general principles of museography and the special possibilities for applying them which are provided by the particular circumstances governing its construction.

There are certain museographical considerations which must have a decisive influence on the structure of the building, for instance, on the arrangement of the rooms or the type of roof chosen, and which are therefore of technical importance in the construction.

Consequently, the successful planning of a museum entails the well-considered choice and unerring application of these deciding principles, whose chief theoretical and practical aspects I shall now briefly describe.

Natural Lighting This is one of the subjects most keenly discussed by museum authorities, and is, indeed, of outstanding importance. It was believed at one time that electric light, being easy to switch on, adaptable and unvarying in its effects and able to give full value to architectural features, might provide not merely an alternative to the use of daylight in museums, but a substitute for it. But experience has forced us to recognize that—especially where running expenses have to be considered—daylight is still the best means of lighting a museum, despite the variations and difficulties which characterize it at different seasons and in different places. The building should therefore be so planned as to make the best use of this source of light, even if certain other structural features have to be sacrificed as a result.

Daylight may come from above or from the side. In the former case suitable skylights will be provided in the ceilings of the exhibition rooms. In the latter case, one or more walls will be pierced by windows, the height and width of which must be decided according to individual requirements (see Fig. 1a-f.).

Lighting from Above This type of lighting, sometimes called overhead lighting (I dislike this term, which seems too restrictive, ignoring the possibility of directing the light from above at any desirable angle), has long been favored by the designers of museums, for it presents certain obvious advantages.

1. A freer and steadier supply of light, less liable to be affected by the different aspects of the various rooms in the building and by any lateral obstacles (other buildings, trees, etc.) which might tend, by causing refraction or by casting shadows, to alter the quantity or quality of the light itself.

2. The possibility of regulating the amount of light cast on the pictures or other exhibits and of securing full and uniform lighting, giving good visibility with a minimum of reflection or distortion.

3. The saving of wall space, which thus remains available for exhibits.

4. The maximum latitude in planning space inside the building, which can be divided without requiring courtyards or light shafts.

5. The facilitation of security measures, owing to fewer openings in the outside walls.

Compared with these advantages, the drawbacks seem trifling and can in any case be reduced or overcome by suitable technical and structural measures. They are:

1. The excess of radiating light, or of diffused light interspersed with irregular rays.

2. The disadvantages inseparable from any system of skylights (increased weight of the roof or ceiling supports; liability to become coated with dirt; risk of panes being broken; danger of rainwater infiltration; condensation of moisture; admission of sun rays; irradiation and dispersion of heat, etc.).

3. The monotony of the lighting, and oppressive claustrophobic effect produced on visitors called upon to walk through a long succession of rooms lit from above.

4. The greater complexity of the architectural and technical problems to be solved in providing a roof which, while adapted to this form of lighting, will effectively serve its various purposes (problems relating to weather-proof qualities, heating, maintenance, cleaning, security, etc.).

Lateral Lighting This is provided either by ordinary windows of various shapes and sizes, placed at suitable intervals in the walls, or by continuous openings; both windows and openings may be placed either at a level at which people can see out of them or in the upper part of the wall.

The solution adopted will be determined by the type of museum and the nature of its exhibits, as the advantages and disadvantages vary from one to another.

Windows at the usual level, whether separate or continuous, have one serious drawback, in that the wall in which they are placed is rendered useless and the opposite wall practically useless, because showcases, paintings, and any other object with a smooth reflecting surface, if placed against the wall facing the source of light, will inevitably cause an interplay of reflections which impedes visibility. These windows will, however, shed full and agreeable light on exhibits placed against the other walls and in the center of the room at a correct angle to the source of light.

Advocates of lateral lighting point out that this is particularly successful in bringing out the plastic and luminous qualities of paintings and sculpture created in past centuries, when artists usually worked by such light.

All this must be considered in conjunction with the proper use of the floor space, the shape, arrangement, and sequence of the different rooms, their size and depth in relation to the outer walls—the aim being to make the most of the sources of light and to obtain the greatest possible uniformity of lighting throughout each room.

A definite practical advantage is, however, that of rendering possible the utmost simplicity and economy in the style of building, permitting the adoption of the ordinary, nontransparent roofing (flat or sloped) customary in the district, and providing, thanks to the side windows, a convenient and simple method of regulating ventilation and temperature in museums which cannot afford expensive air-conditioning apparatus.

Another advantage of windows placed at the ordinary level is that some of them can be fitted with transparent glass, allowing pleasant views of the countryside, gardens, or architecturally interesting courtyards. This provides a

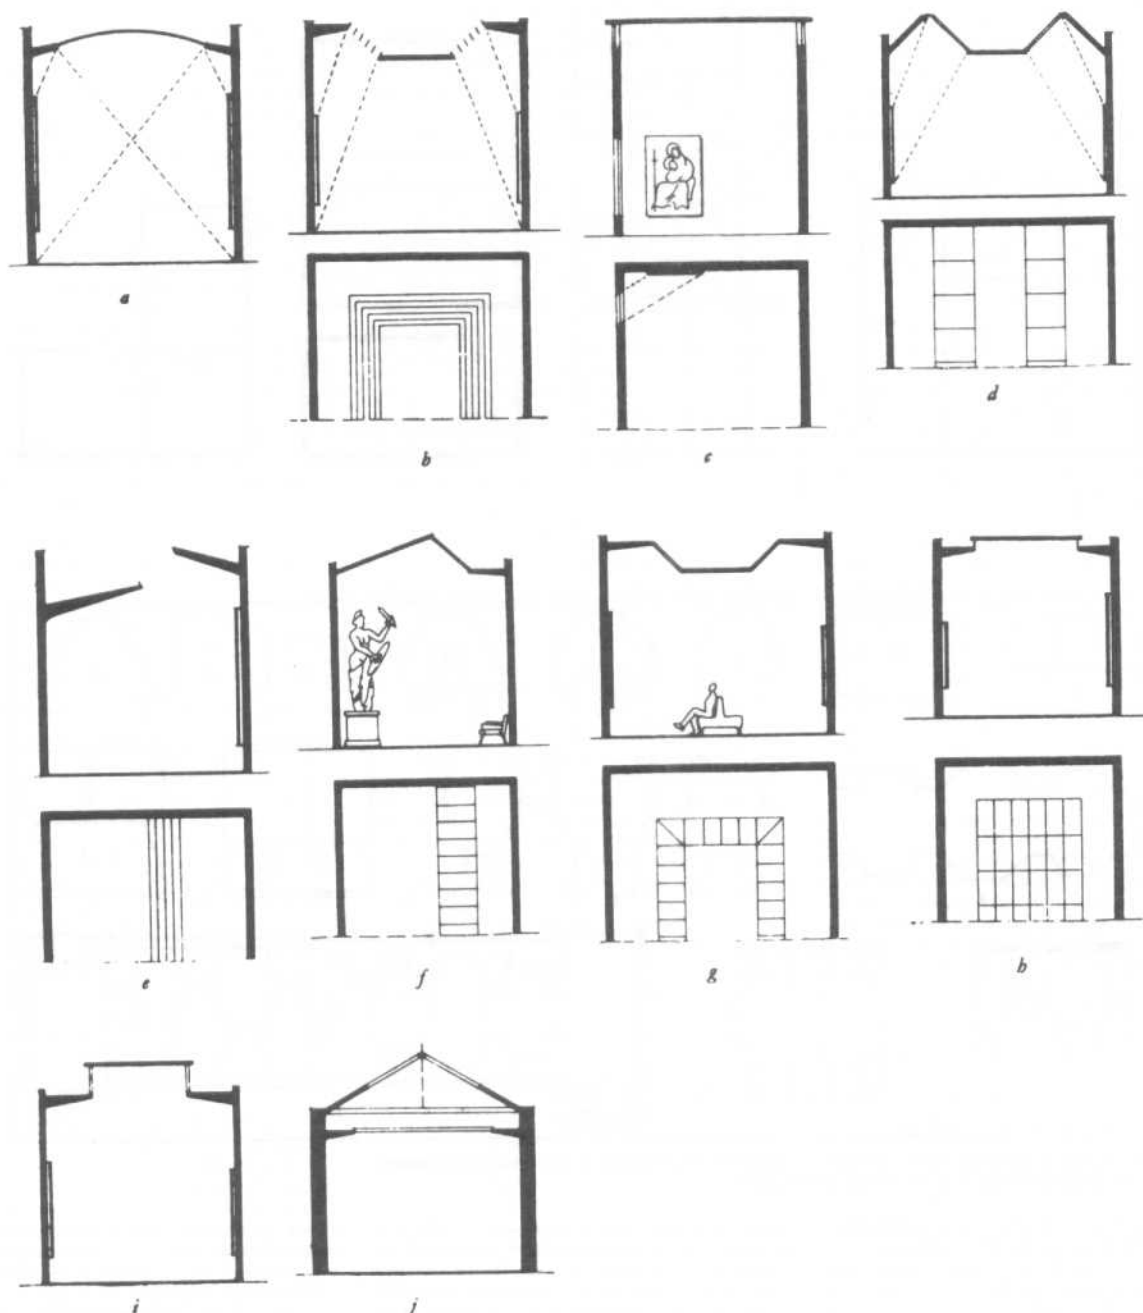

Fig. 1 Different methods of admitting natural light from above. (a) Cross section. (b) to (h) Cross section and view from above. (i) and (j) Cross section.

diversion, resting the visitor's eyes and refreshing his mind.

For this purpose it may be wise, even where overhead lighting is adopted, to arrange a few lateral openings for the passing visitor.

High-placed windows, especially if they occupy more than one wall, provide more light, more closely resembling that supplied by skylights, and leave all four walls free for exhibits: but as they must be placed at a considerable height, if visitors are not to be dazzled, the rooms must be comparatively large and the ceilings lofty. This means that considerable stretches of wall will be left blank, and building expenses will increase owing to the larger size of the rooms.

The tendency nowadays is to abandon uni-

form lighting in favor of light concentrated on the walls and on individual exhibits or groups of exhibits, which are thus rendered more conspicuous and more likely to attract the visitor's attention. Consequently, instead of lighting the whole room, it is found preferable to light the showcases from within, either by artificial lighting or by backing them with frosted glass which admits daylight from outside.

This is a possibility which the architect of a small museum can bear in mind, making use of it in special cases and for objects (glass, ceramics, enamels, etc.) whose effect can be heightened by such lighting. But it entails special structural features which may complicate the general budget.

Moreover, if the lighting system is too rigid,

too definitely planned to suit a particular setting and to establish certain relationships between that setting and the exhibits, it will form an impediment by imposing a certain stability, tending to reduce the museum to the static condition from which modern institutions are striving to emerge—the present-day being that a museum should make a lively, dynamic impression.

It therefore seems preferable, especially in small museums, to choose an intermediate system which can be adapted to varying needs and necessary changes, even if it thus becomes more difficult to achieve ideal results.

Utilization and Division of Space In designing a museum the architect will also be decisively in-

Fig. 2 (a) to (d) Floor plans for the location of doors in relation to the use of space. (a) 1 — Traditional location of doors. 2 to 8 — Secondary doors. 9 to 15 — Polygonal enclosures.

fluenced by the way in which it is intended to utilize and divide the space to be devoted to the displays. This, too, is of course closely connected with the question of lighting, which we have already discussed.

The modern tendency is to create large unbroken spaces, which can then be divided up by movable partitions or lightweight structures, to be grouped or displaced as required.

The traditional system is the contrary one of dividing the space, by means of permanent walls, into rooms of various sizes, which may be either communicating or independent (connected, in the latter case, by passages or side galleries) (see Fig. 2a-e).

A small museum may do well to adopt an intermediate system with a succession of average-sized rooms (for the display of permanent collections whose contents will not change, such as those received through bequests, donations, etc.) and one or more large rooms which can be variously divided up when required by movable partitions or light structures.

The structure of the building and, with it, the interior and exterior technical features,

will vary according to the purpose for which it is intended. Requirements and costs will be different in each separate case, for it is evident that the larger the surface to be roofed in one span without intermediate supports, the greater the technical problem and the cost of the roof. Furthermore, the architect's calculations for the various features of a coordinated project (plan, circulation, lighting, etc.) will not be the same if the project relates to rigid construction subdivided by permanent walls, or to flexible construction, adjusted to the changes periodically effected in the museum.

Museum Services Before considering the planning of the museum it is essential to determine the size and location of the various services. In other words, we must decide how much space can and should be allocated for subsidiary activities, or for those necessary to the functioning of the museum in its relationship with the public (offices, rooms for meetings and lectures, library, documentation service) on the same floor as the exhibition rooms, and which services and technical plant (heating and electrical apparatus, storerooms, work-

shops, garage, etc.) can be housed in the basement or, if possible, in special outlying buildings to be built as annexes, at a convenient distance from the main building.

It should be remembered that the usual custom is to set aside for these purposes an area which may be as much as 50 percent of the total space available. In small museums this proportion may be reduced. But the fact remains that two conflicting needs have to be reconciled: on the one hand there must be easy communication between the public rooms and the museum services, since this makes for smooth relations between visitors and staff; on the other hand it must be possible to separate these two sections, so that they can function independently at any time. This is necessary chiefly to safeguard the collections at times when the building is closed to the public while the curators or office staff are still at work and the library and lecture hall in use.

Planning

It is hardly necessary to explain, before em-

barking upon a discussion of the different questions that may arise when a small museum is being planned and built, that my aim is merely to put forward certain suggestions to serve as practical pointers, based on experience of the subject, with no intention of trespassing upon the domains of the various technical authorities who must inevitably be consulted.

The Exterior A museum which is to be built in an isolated spot or reserved space (park, garden, etc.) needs to be surrounded by an enclosure, especially if the site forms part of an extensive area. For the visitor, this enclosure will provide a foretaste of the museum's architecture, and thus must not constitute a "psychological barrier," though the fundamental aim of security, which it has to serve, must not be sacrificed.

If, on the contrary, the museum is to overlook a public street, it will always be advisable: (a) to separate it from the stream of traffic by a belt of trees or even by flowerbeds; (b) to set back the entrance in a quiet corner; (c) to allow space for a public car park.

The architect should think of the building he has been asked to design as an organism capable of growing, and therefore provide from the outset for suitable possibilities of expansion, so that when the time comes for this it will not require far-reaching and costly alterations. He should regard the portion to be built as the nucleus of a cell, capable of multiplying itself or at least of joining up, according to plan, with future enlargements.

Where space permits, it is best to allow for horizontal expansion, as this, though more expensive, has the twofold advantage of enabling all the display rooms to be kept on one level and of leaving the roof free for overhead lighting.

Renouncing all pretensions to a monumental style, the outward appearance of the building—especially if overhead lighting is adopted, so that there are no windows to break the surface—should be distinguished by a simple balance of line and proportion and by its functional character.

Arrangement Any general plan of construction which entails an apportionment of premises is closely bound up with the purpose of the museum and the nature, quality, and principal components of its collections. Each type of museum has different requirements, which may be met by various architectural methods.

It is difficult to give any exact classification of the different types of collections, but we can offer a very brief one, if only to indicate the wide range of demands the designer of a museum may be called upon to meet:

1. *Museums of art and archaeology.* The size of the rooms and height of the ceilings will be determined by the nature and dimensions of the works to be exhibited. It is not difficult to calculate a practical minimum capable either of accommodating old paintings, which are usually large, or medium-sized modern canvases; a suitable room might measure about 16 by 23 ft, with wall accommodation to a height of about 14 ft. In the case of furniture, or of examples of decorative art (metal, glass, ceramics, textiles, etc.) to be displayed in showcases, the ceiling need not be as high. If pictures and sculpture are to be shown separately, their settings must be different from the point of view of space and lighting. For silver, jewelry, or precious objects, it may be better to use showcases set in the walls—which can thus be equipped with locking devices and anti-burglar safeguards—lit from within, the rooms being left in semi-darkness. Rooms lit by artificial means rather

than by sunlight are best for drawings, engravings, watercolors, and textiles. Such rooms may be long and narrow rather than square—rather like corridors or galleries—as the visitor has no need to stand back in order to look at the exhibits, which will be arranged in showcases against the longest walls.

2. *Historical or archival museums.* These need less space for the showcases in which their exhibits are placed, and comparatively large and numerous storerooms for the documents kept in reserve. Relics and papers are best shown in rooms equipped with suitable protective devices and artificially lighted, though some use may also be made of indirect natural light.

3. *Ethnographic and folk museums.* The exhibits are usually displayed in showcases. They are often large and cumbersome, requiring a good deal of space. Considerable space is also needed for reproducing typical surroundings, if this is done with genuine pieces and properties or full-sized replicas. Strong artificial lighting is generally used as being more effective than daylight.

4. *Museums of physical and natural sciences, technological or educational museums.* Owing to the great variety of collections involved, their division into sections and the necessary scientific cataloging, these museums differ in size and in architectural and functional characteristics. Where the exhibits are arranged in series (minerals, insects, fossils, dried plants, etc.), medium-sized rooms may suffice, whereas reconstructions and built-up displays of animals or plants demand considerable space and special technical features (for instance, means of keeping the special materials and preparations in good condition, unaffected by the atmosphere, or equipment for maintaining aquaria, permanent film displays, etc.). This type of museum needs laboratories for the preparation and upkeep of certain exhibits (stuffing, drying, disinfecting, etc.).

It thus rests with the architect to decide, for each of these types of museum, what arrangement will best satisfy the particular conditions, purposes, and requirements involved.

There can never be any objection to adopting the modern principle of a building so constructed that its interior can be adapted, divided, and altered to meet the varying demands of successive exhibitions. If this is done, the most important thing is that the construction shall be "flexible," that is, capable of adaptation to the different features it must simultaneously or successively contain, while preserving unchanged its general framework—entrances and exits, lighting system, general services and technical installation. This principle is particularly valuable in small museums and in any others which must allow for enlargements not always foreseeable at the outset.

The internal arrangement of the available space, the distribution and style of the galleries can then be either temporary or comparatively permanent. In the former case, use will be made of movable partitions, panels of lightweight material (plywood or thin metal frames covered with cloth, etc.) fitted into special supports or into holes or grooves suitably placed in the floor; these can either be separate or arranged in groups held together by bolts or hinges.

This system is very practical for small museums which intend to follow a definite cultural program including successive loan exhibitions of works of art, and are therefore obliged to make frequent changes, dictated by circumstances, in the size and appearance of their galleries. It has, however, the draw-

backs that all the interior structure is independent of the outer walls of the building and made of comparatively fragile materials which are expensive to keep in repair; moreover the place never looks settled, but rather mechanical and disjointed—an effect which is displeasing to the eye unless the architect designs the component parts with great taste.

Other objections to this method include the difficulty of preparing new catalogs and guides to keep pace with the changes, and of overcoming the conservatism of a great proportion of the public; and, above all, the consequent impossibility of arranging circulation within the building, and other matters affecting the division of space on a permanent basis. These things have to be left to the organizers of each successive exhibition, and therefore cannot be included in the architect's original plan.

If, on the other hand, the interior space is to be divided up in a more or less permanent manner, the question of "flexibility" being set aside until the comparatively distant time when the original plan of the museum comes to be radically altered, then the dividing walls can be really "built" to last, even if lightweight materials are employed. For their role will be reduced to providing a background for works of art, for showcases, or for any exhibits hung on them, and to supporting their share of whatever type of roof or ceiling is chosen.

In this case the interior arrangement will be very similar to, if not identical with, that of a museum of the traditional type, planned as a complete building with all its sections permanently fixed and the size and shape of its rooms settled once and for all.

In this kind of structure it is more than ever necessary to plan with a view to enabling the public to circulate and to arranging the collections and services in the most rational and functional manner possible.

The question of circulation must be studied attentively, so that the arrangement and the itinerary will be clear not only to anyone looking at the ground plan of the museum but also to anyone walking through the rooms. It should be planned to fit the logical order of the exhibition, whether that order is governed by chronology, by the nature of the material displayed, or as in a scientific museum, aims at providing a connected sequence of practical information.

Though a compulsory, one-way route may not be entirely desirable in a large museum, it is satisfactory and one might say logical in a small one, as it saves space and facilitates supervision. Visitors should not have to turn back and return through rooms they have already seen, in order to reach the exit. They should, however, be able to turn off on their way round if they wish to cut short their visit or confine it to certain things that particularly interest them.

So, even if a museum is to show a series of selected works of the first quality, we should consider the possibility of arranging them in proximity to one another in such a way that they can be seen without the necessity of traversing the entire building. For example, in a succession of rooms surrounding an inner courtyard (see Fig. 3).

Care should always be taken, however, to avoid the confusion of too many adjacent doors, or of rooms running parallel to one another; visitors must not be made to feel that they are in a maze where they can easily lose their way.

If the designer's preference or the demands of space result in a series of rooms all set along the same axis, it may be desirable to connect them by a corridor. But this should not be the only means of access to the rooms, for if the visitor is forced to return to it each

Fig. 3 Suggested floor plan for a small museum.

time, fatigue and bewilderment will be much increased.

Entrance However many outside doors may be found necessary for the various museum services (but these should be as few as possible, to facilitate supervision and security measures), there must be only one public entrance, placed quite separately from the others. This should lead into a vestibule where certain essential services will be located—sale of tickets, information service, and sale of catalogs and postcards. In a small museum one person will of course be responsible for

all this, and the necessary installation must be carefully planned to ensure the most practical form and arrangement. The official in charge should not be confined to a booth behind a window, but should be able to move about freely and leave his [her] position when circumstances require.

In a little museum it would be particularly unsuitable to design the entrance hall on a massive or pompous scale, as was customary in the past, making it unnecessarily lofty, and to decorate it in would-be monumental style, like the atrium of a classical temple, with arches and pillars. Modern architects tend increasingly to reduce overhead space and give the greatest possible width and depth, producing a balanced effect of greater intimacy and attraction. It is important for the entrance hall to seem attractive even to the casual passerby—who is always a potential visitor to the museum. It should provide an easy introduction to the building, a point from which the individual visitor can find his way without difficulty and where large parties can be greeted and assembled. It must therefore be fairly spacious, and provided with the strict minimum of sturdily built furniture (one or two tables for the sale of tickets, catalogs, etc., a cloakroom, a few benches or chairs, a notice board, a general plan of the museum to guide visitors, a clock, and perhaps a public tele-

phone booth and a letterbox). It is not advisable to have only one door from here into the exhibition rooms; there should be two, an entrance and an exit, far enough apart to prevent delay should there be a crowd but placed in such a way that both can be easily watched at the same time.

In museums where arriving and departing visitors are to be mechanically counted, an automatic turnstile should be installed, serving both doors but placed at a sufficient distance from the main entrance and the ticket office. Another possible method is that of the photoelectric cell, but the objection to this is that when visitors are crowding through the turnstile the record may not be accurate. In museums where admission is free, attendance can be computed for statistical purposes more simply by the custodian with a manual counter—which will avoid adding an unnecessary complication to the fittings of the entrance hall.

Exhibition Rooms—Shape and Requirements A museum in which all the rooms are the same size becomes very monotonous. By varying their dimensions and the relation between height and width—and also by using different colors for the walls and different kinds of flooring—we provide a spontaneous and unconscious stimulus to attention (see Fig. 4a-f).

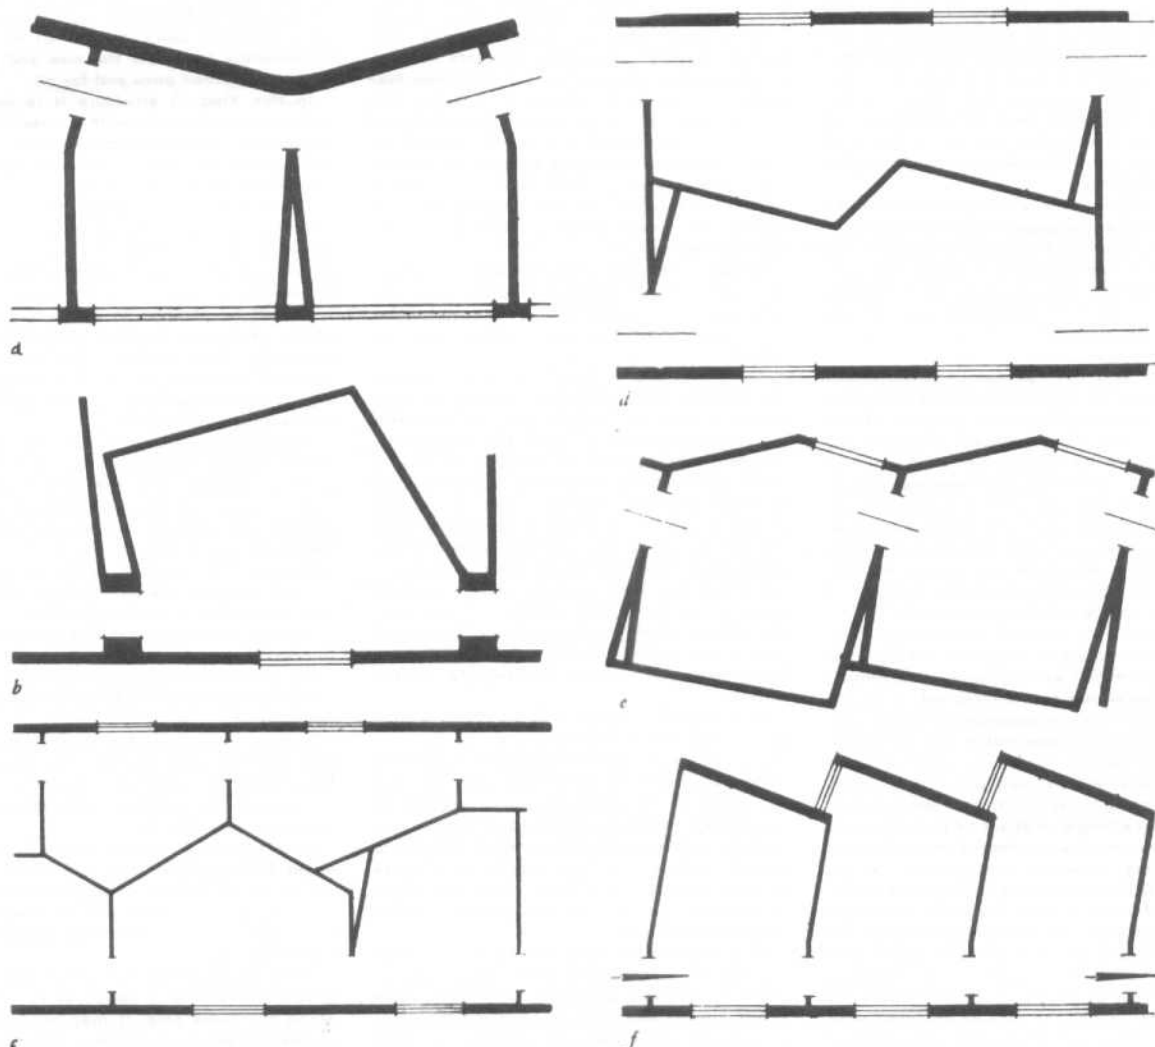

Fig. 4 Different ways of dividing up exhibition space.

Fig. 5 In 1942, Mies van der Rohe devoted a great deal of attention to the theoretical design of a museum for a small city to provide a setting for Picasso's painting *Guernica*. The building is designed to be as flexible as possible, consisting simply of a floor slab, columns, roof plate, free-standing partitions and exterior walls of glass.

The relative "absence of architecture" intensifies the individuality of each work of art and at the same time incorporates it into the entire design.

One of the museum's original features is the auditorium which consists of free-standing partitions and an acoustical dropped ceiling.

Two openings in the roof plate (3 and 7) admit light into an inner court (7) and into an open passage (3). Outer walls (4) and those of the inner court are of glass. On the exterior, free-standing walls of stone would define outer courts (1) and terraces (10). Offices (2) and wardrobes would be free-standing. A shallow recessed area (5) is provided, around the edge of which small groups could sit for informal discussions. The auditorium (8) is defined by free-standing walls providing facilities for lectures, concerts and intimate formal discussions. The form of these walls and the shell hung above the stage would be dictated by the acoustics. The floor of the auditorium is recessed in steps of seat height, using each step as a continuous bench. Number (6) is the print department and a space for special exhibits. Number (9) is a pool." (From P. C. Johnson, "Mies van der Rohe," Museum of Modern Art, New York, 1947.)

Monotony also results when a number of rooms follow one another in a straight line. Even where this cannot be entirely avoided, the rooms should be so constructed that the doors are not opposite one another, providing a "telescopic" view through the building. An uninterrupted prospect of the long route ahead is usually found to have a depressing effect on visitors.

There are, however, undoubted advantages in being able to see into several rooms at the same time; it is a help, for instance, in directing visitors, and for security purposes.

On the other hand, by varying the positions of the doors we are also able to place the visitor, from the moment of his entrance, at the point chosen by the organizer of the display as the best for conveying an immediate and striking impression of its general contents, or for giving a view of the most important piece in that particular room. In principle, the door should be placed in such a way that a visitor coming through it will see the full length of the opposite wall. It is therefore not advisable for it to face a window, since the visitor will then be dazzled just as he comes in.

With regard to the shape and size of the rooms, I have already pointed out that dimensions should be varied so as to stimulate the attention of the public and should also be adapted to the size of the exhibits.

I ought perhaps to repeat here, for the sake

of clarity, that the form and size of the rooms will also depend to some extent on the lighting system chosen. Overhead lighting allows greater diversity of shape (rectangular, polygonal, circular, etc.) because the lighting can always be arranged on a scale to suit the room. Oblong rooms, divided by partitions to a certain height, but with one ceiling and skylight, should however be avoided; this system has proved unsatisfactory both from the aesthetic and from the functional points of view.

The practice of rounding off the corners of rectangular rooms is also going out of fashion, as it has been found that the advantage of unbroken walls and the impression of better use of light in a more compact space are offset by the resultant monotony, and that the general effect is not pleasing to the eye.

Lateral lighting requires shallow rooms, their walls set at an oblique angle to the source of light. But the larger the windows, the more difficult it becomes to prevent light from being reflected in the works placed against the opposite wall. It is undeniably difficult to give a pleasing appearance to these asymmetrical rooms; the taste of a fine architect is needed to give them character and harmony, either by careful attention to spatial proportion or by the use of different colors for the walls and ceiling.

Theoretically, the door between two laterally lit rooms should be placed near the wall next

to the windows, because otherwise the two walls meet in a dark corner where nothing can be exhibited. But if the daylight is admitted not through a vertical or comparatively narrow window, but through a "ribbon" of glass running the whole length of the wall, the problem is not the same. In this case the two end walls, meeting the outside wall from the normal direction, or at a slight angle, will be well lit throughout their length; the doorways can therefore be placed at the furthest extremities, thus adding to the effective depth of the room.

One important fact should be remembered when the shape of the rooms is being decided. A square room, when it exceeds a certain size (about 23 sq ft), has no advantage over an oblong one, either from the point of view of cost (roof span) or from that of the use of space in the satisfactory display of the exhibits, especially if they are paintings.

It is sometimes found advisable to place a work of art of outstanding interest and exceptional value in a room by itself, to attract and concentrate the greatest possible attention. Such a room need be only large enough to accommodate a single work; but there must always be enough space for the public to circulate freely. Galleries intended for permanent exhibitions may, on the contrary, be of considerable size, though it is never advisable for them to be more than about 22 ft wide, 12 to 18 ft high, and 65 to 80 ft long.

SMALL MUSEUMS

PLANNING THE SMALL MUSEUM

The objective of the proposed museum should be clearly defined, as well as the geographic region, the subject (history, natural history, or art) and extent of display and other services.

The following is an example of a suitable basic statement for a small museum:

The basic objective of the Museum is to collect, preserve, study and exhibit significant objects of the community, and provide related educational services in order to increase public knowledge and stimulate creative activity.

This statement should have further definition by incorporating a reference to the type of collections, whether human history, natural history or art.

A good museum includes these basic functions: (1) curatorial, (2) display, (3) display preparation, (4) education. In order to realize both objectives and functions, certain facilities and spaces are essential.

There must be sufficient diversification of spaces to allow each function to be undertaken separately while at the same time combining certain activities in a single area as required for economy in a small museum. Because of the many and varied kinds of tasks which a museum has to perform, it is absolutely impossible to maintain good housekeeping and curatorial procedures without separation of functions into separate rooms. This relation between functions and physical facilities is summarized in the following.

Functions	Space required
1. Curatorial Functions	
a. Collection, preservation, identification, documentation, study, restoration.	a. Office-workroom, Workshop
b. Storage of collections.	b. Reserve Collection Room
2. Display Function	
Thematic and changing displays of selected objects and documents from the collections arranged to tell a story.	Display Gallery
3. Display Preparation Function	
The preparation of exhibits.	Workshop, Office-workroom
4. Educational and Public Functions	
This term has been expanded to include all public functions.	
a. Lectures, school tours, society meetings, films, and social functions.	a. Lecture room, Chair storage closet, Kitchenette
b. Reception, information, sales, supervision of display gallery.	b. Lobby Sales and Information Counter
c. Public requirements.	c. Cloak room, Washrooms
5. Other Services	
a. Mechanical.	a. Heating-ventilation plant
b. Janitorial.	b. Janitor's closet

Canadian Museums Association, Ottawa, Ontario, 1966.

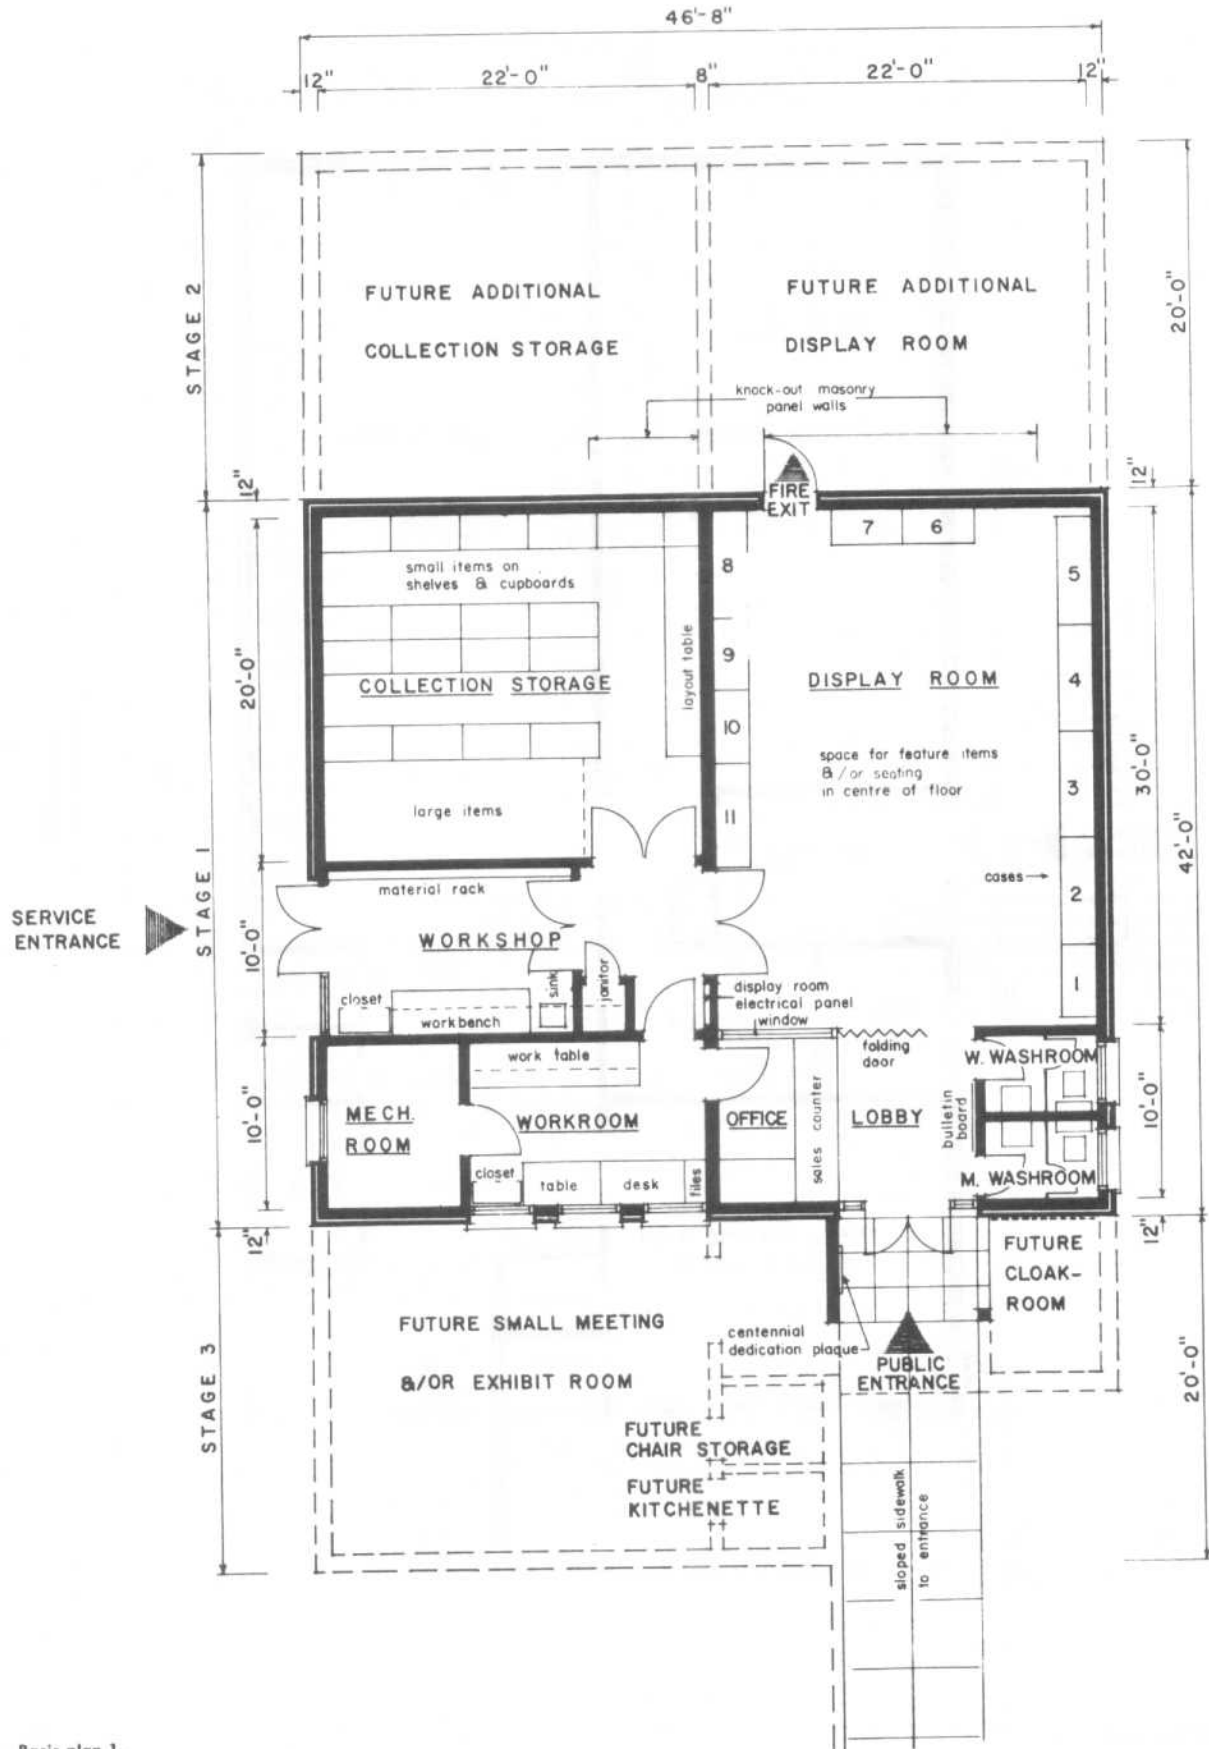

Fig. 2 Basic plan 1.

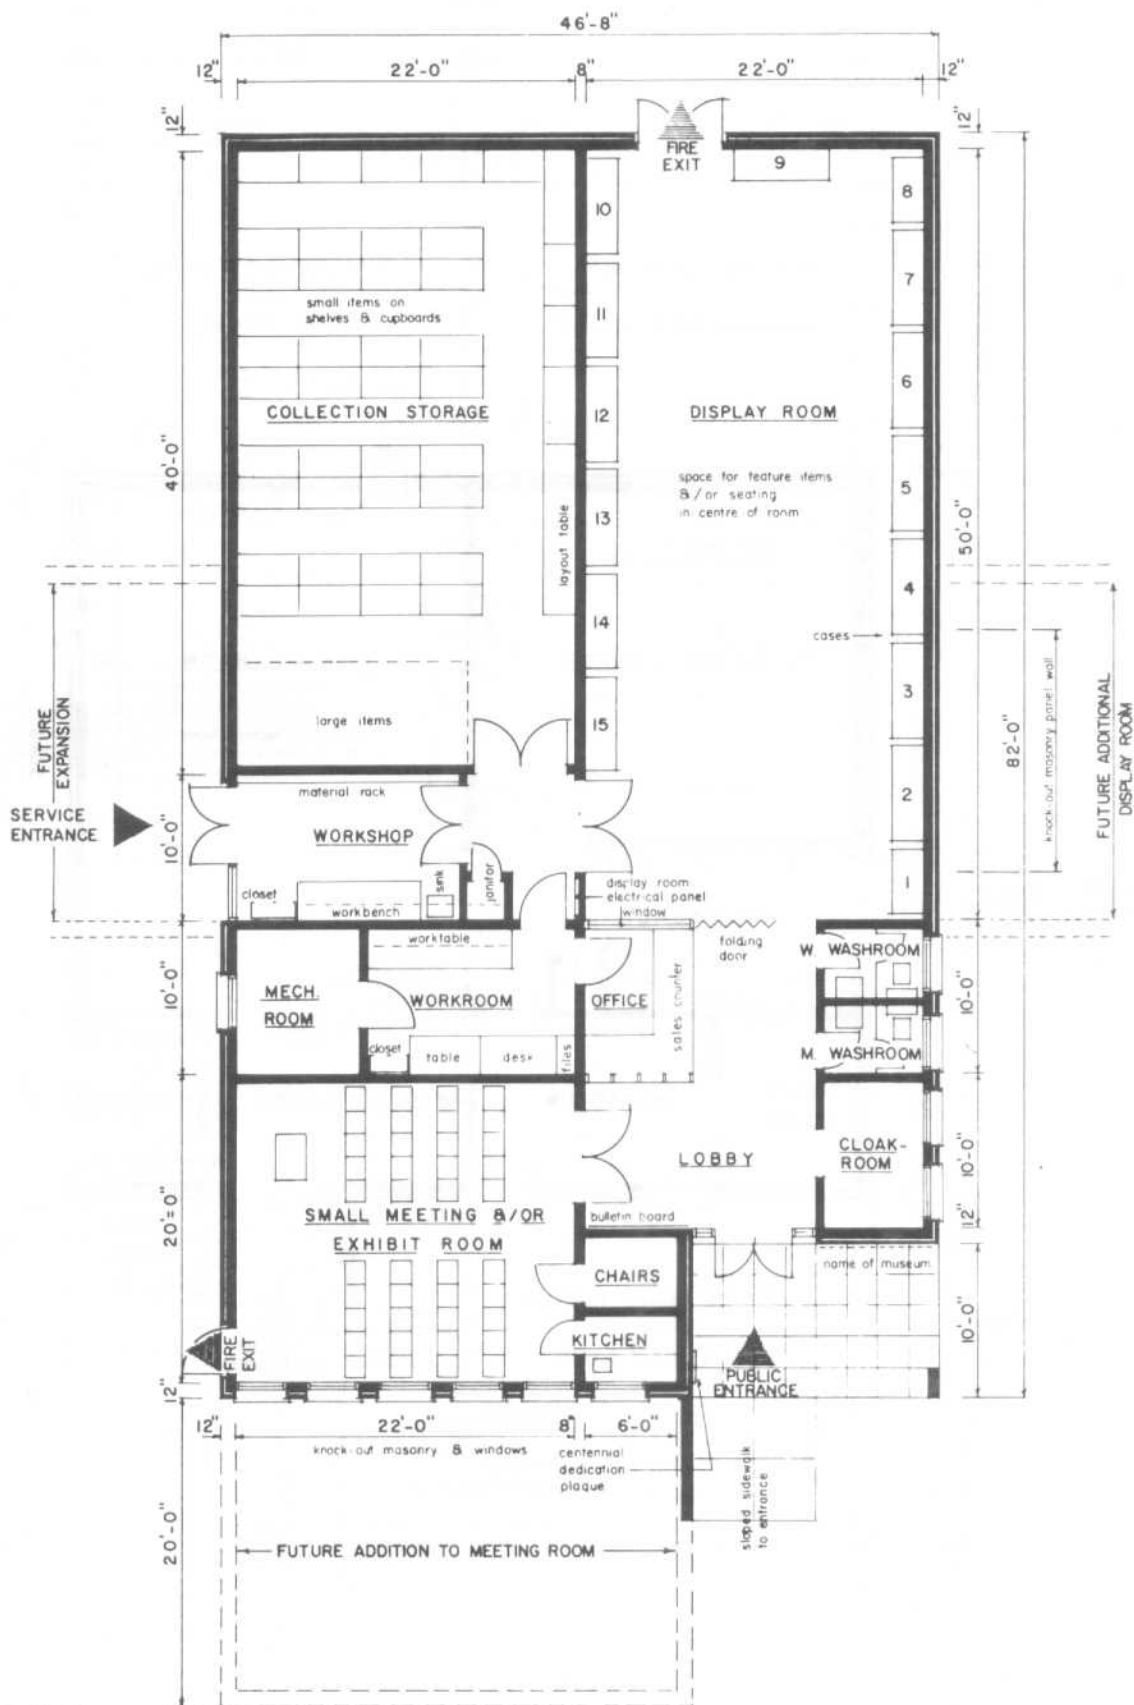

Fig. 3 Basic plan 2.

ORGANIZATION OF SPACE

The next step in the planning of a museum is the working relationship between these various functions. The planning of a good museum must reflect the most efficient manner in which the various tasks are carried out individually and in relationship to each other, without one adversely affecting the other. A major consideration in this planning is the matter of future expansion and construction in several stages.

The diagram (Fig. 1) illustrates the most efficient working arrangement.

To illustrate the manner in which a good small museum may be planned on the basis of the organizational diagram, three basic plans are presented as examples, ranging from the smallest possible at 1960 sq ft, up to 3823 sq ft, and therefore representing three different capital expenditures and operating costs. All plans incorporate provisions for future expansion and construction in several stages as a basic principle.

It should be further noted that the museum plans shown are based upon collections comprising smaller types of specimens and artifacts. Large equipment, vehicles, and farm machinery would require considerably more space although the basic functions outlined earlier would still apply. The following is a summary of some main features.

Basic Plan 1

This plan (Fig. 2) shows the absolutely minimum sizes of spaces required for an effective minimum museum. It will be noted that the display area is only about 40 percent of the area of the building.

Future expansion of the existing collection storage room can take place as the collections grow, while the existing display room also can be increased in size as required. Future addition of a lecture room off the lobby can also be achieved so that the educational functions of the museum can be expanded. Note that these additions can be made without complication to the roof structure of the original plan. The number of perimeter display cases shown would be ample to maintain and ensure changing displays.

Basic Plan 2

This (Fig. 3) is an expansion of Plan 1, with allowance for further expansion of the display, collection, and educational functions in the future. The number of perimeter cases shown would be ample for the story theme and changing exhibits while the center of the room may have larger items, photographic panels or special feature displays. The display room is 33 percent of gross.

GALLERY DESIGN*

The average American museum visitor (Fig. 4), if a man, is about 5 ft 9¼ in tall, and his eye level is 5 ft 4¾ in; the average woman is about 5 ft 3¾ in tall, and her eye level is 4 ft 11¼ in. Thus, the mean adult eye-level height is about 5 ft 2¼ in. With little eye movement, people usually see and recognize with ease things that are within an approximately elliptical cone of vision, with the apex of the cone at the eye-level height. Studies have shown that, in general, the

Fig. 4 Measurements of adult and six-year-old visitors in relation to cases.

Fig. 5 Difficulties encountered in viewing details more than 3 ft below or 1 ft above one's eye level.

adult museum visitor observes an area only a little over 1 ft above his own eye level to 3 ft below it at an average viewing distance of 24–48 in (Fig. 5). Arranging objects and labels above and below these limits places a strain on seldom-used muscles and produces aching backs, tired feet, burning eyes, and stiff necks. Some quite large objects, such as totem poles or dinosaurs, will inevitably soar above these viewing limits, and, in this event, the visitor must be permitted space to back far enough away from the object to comprehend it without becoming a case for an orthopedic specialist (Fig. 6).

The flow of visitors is like the flow of water in a stream. If the cases are arranged with gently curving lines to take advantage of this pattern of movement (Fig. 7b), visitors will find the room more attractive and can progress easily with the line of the case. Often the arrangements can be staggered (Fig. 7c) which produces a certain mystery and a desire on the part of the visitor to peek around corners to see what is next. It is not always necessary to have a wide opening into a hall. Cases that are arranged to narrow the entrance a bit (Fig. 7d), so that the hall inside then opens out, provide a certain amount of interest.

Fig. 6 Viewing distance should increase with greater size of object.

DIAGRAMS OF ESSENTIAL LIBRARY ELEMENTS

Three diagrams have been prepared as an aid to visualizing the functional relationships of the principal areas in typical small libraries. These diagrams are for libraries for towns of 5,000, 10,000 and 25,000 persons respectively.

They are meant to clarify relationships and circulation patterns. They definitely are *not* building plans, nor do they constitute the only possible relationships between the program elements. It is intended that they assist in understanding the interrelationships between the major program elements.

They are intended to suggest a starting point for the planning of the library and represent *minimum standards*. They are derived from "Interim Standards for Small Public Libraries: Guidelines Toward Achieving the Goals of Public Library Service." ALA—Public Library Association, Chicago, 1962. (See Table 2 on p. 345.)

I. The Library for the Town of 5,000 Population

The basic principles when planning for the library (Fig. 1) are:

1. Location to insure maximum accessibility
 2. Simplicity of design concept
 3. Ease of supervision by library staff
 4. Provision for future expansion
- The basic statistics of the library are:

Staff: One and one-half persons, including a professional librarian and a part-time assistant.

Book Collection:	15,000 volumes
Space for book collection:	1,000 sq ft
Space for readers:	700 sq ft
Staff work space:	500 sq ft
Estimated additional span for utilities, circulation, and miscellaneous:	800 sq ft
Total estimated floor space:	3,500 sq ft

These are approximates only and will, of course, vary with each community.

II. The Library for the Town of 10,000 Population

This library (Fig. 2) in many respects is an expanded version of the first one. The basic principles and relationships are the same. The staff and space requirements are approximately twice those of the first.

The larger size permits the development of special areas that add to the usefulness of the library and enable it to provide better services. Some of these may be: a special area in the children's section for storytelling and related activities, expanded reference, and separate periodical areas. A small meeting room may be a useful addition to the program.

The basic requirements for this library are:

Staff: Three persons: a professional librarian, an assistant, and part-time clerical and page help equivalent to one full-time person.

Size of book collection:	20,000 volumes
Space for the book collection:	2,000 sq ft
Space for readers (40 seats min.):	1,200 sq ft
Staff work space:	1,000 sq ft
Estimated additional space for utilities, circulation, and miscellaneous:	2,800 sq ft
Total estimated floor space	7,000 sq ft

III. The Library for the Town of 25,000 Population

This library (Fig. 3) in function is more complex than the previous libraries. To the three basic functional areas of the library, which are expanded and elaborated on, there usually is added a fourth, a community function, often in the form of a meeting room or small auditorium. There may also be (Fig. 4):

- Special exhibition space
- Special exhibition rooms
- Study area with carrels near the stacks
- Small meeting rooms
- Audiovisual rooms or booths

The circulation pattern is more complex. A separate entrance for children is highly desirable. Access to the community facility by the public after normal library hours is required. A library of this size may be a two-level structure. On the diagram (Fig. 3) we have indicated these circulation requirements. Note the separate staff and public circulation between levels. The basic requirements for the library for the town of 25,000 persons are:

Staff: Ten—this might be broken down to include two professional librarians, a college graduate, three assistants, and four other persons, divided between clerical and pages.

Space for book collection:	5,000 sq ft
Reader space (minimum of 75 seats):	2,250 sq ft
Staff work space:	1,500 sq ft
Estimated additional space required for special uses, utilities, and miscellaneous:	6,250 sq ft
Total estimated floor space:	15,000 sq ft

BRANCH LIBRARIES

A branch library can play an important role as a cultural center. In addition to providing books, it can provide record and tape lending, music-listening facilities, visual-aid facilities, and lecture series as well as act as a general information center. With such an expanded role, the library or cultural center will be an important element in the neighborhood. Figs. 1 and 2 are possible floor plans.

Regardless of the size of the community, its library should provide access to enough books to cover the interests of the whole population.

Manual of Housing/Planning and Design Criteria, De Chiara and Koppelman, Prentice-Hall, Inc., Englewood Cliffs, N.J., 1975.

1. Libraries serving populations from 5,000 to 50,000 require a minimum of 2 books per capita.

2. Communities up to 5,000 persons need access to a minimum of 10,000 volumes, or 3 books per capita, whichever is greater.

The library building should provide space for the full range of library services. All libraries should have designated areas for children's, young adult, and adult materials.

Multipurpose rooms should be provided for meeting, viewing, and listening by cultural, educational, and civic groups unless such facilities are

readily available elsewhere in the community. They should be located for easy supervision so that they may be used for quiet reading and study when not needed by groups.

No single type of building is satisfactory for all public libraries. Each building is likely to be different, and its differences should be directly related to its service program.

The library building should be located in or near the community shopping center and at street level if possible. Adequate parking should be available nearby.

SPACE REQUIREMENTS

The program statement, which includes objectives, activities, and requirements, will spell out total needs in terms of square feet of floor space. Generally speaking, the total need may be divided into five categories: space for (1) books, (2) readers, (3) staff, (4) group meetings, and (5) mechanical operations and all other (stairways, elevators, toilets, etc.). Actual space allocations will tend to vary in accordance with the library service program in relationship to community needs.¹ Table 1 provides general guidelines for programming the total building, and Table 2 provides guidelines for interior space in relation to population and size of the book collection.

Space for Books

To a large extent the amount of book shelving required will depend on the size of the library service area and whether the library is a member of a library system. Most library planners, when estimating the size of the book collection, apply a standard which ranges from three books per capita (smallest communities) to one and one-half books per capita (largest cities). In any event enough book shelving should be provided to plan for 20 years' anticipated growth.

The program statement should also include a detailed analysis of the amount of shelving needed. It should be presented in terms of category, location, and linear feet. Categories found in nearly all public libraries include adult fiction and nonfiction; children's books; books for young adults; reference books; bound, unbound, and microfilmed newspapers; bound, unbound, and microfilmed periodicals; local history books; less used books for the bookstacks; and special subject collections. Allowances should be made also for nonbook materials (i.e., phonograph records) which are often accommodated on library shelving.

Despite the fact that there is considerable variation in the size of books, there are several reliable formulas which may be used to estimate the amount of space required for books. These are: open reading rooms, 7 volumes per lineal foot, or 50 books per foot of standard height wall shelving, or 100 books per foot of double-faced shelving; bookstack areas, 15 books per square foot (includes aisles), or 2

books per cubic foot. Approximately 50 long-play phonograph records may be shelved in one lineal foot of wall shelving. It is important to note that these formulas are given for full capacity. Under normal conditions, one-third of each shelf should be left for future expansion. (See Figs. 1 to 3.)

Space for Readers

Reader seating requirements should be determined for at least 20 years ahead. Two principal sources of information which library building planners will find equally useful for this purpose are first, a careful analysis of

Fig. 1 Optimum shelving conditions for adults.

Fig. 2 Optimum shelving conditions for teen-agers.

Fig. 3 Optimum shelving conditions for children.

LIBRARIES

Space Requirements

purely local needs, and second, existing, time-proven formulas applied as a basic guide.

The most important factor in determining reader space needs is of course the reading potential of the people who will use the library. A conveniently located, attractive library will stimulate dramatically increased library use. Serious errors can result when estimates are based on use of the old, existing library.

As noted earlier an additional problem that must be carefully evaluated is providing an adequate number of seats for use by readers during peak periods. This problem has been intensified in recent years due to the increase in school attendance and the newer methods of instruction which involve extensive use of reference and supplementary materials by students of all ages. Since these periods of peak use occur irregularly, it is not economical to provide reading rooms which will be large enough to accommodate abnormally large crowds. Therefore, some libraries have attempted to solve this problem by locating multipurpose rooms adjacent to adult reference

TABLE 1 Experience Formulas for Library Size and Costs

Population size	Book stock — volumes per capita	No. of seats per 1,000 population	Circulation — volumes per capita	Total sq ft per capita	Desirable, first floor, sq ft per capita
Under 10,000	3½-5	10	10	0.7-0.8	0.5-0.7
10,000-35,000	2¾-3	5	9.5	0.6-0.65	0.4-0.45
35,000-100,000	2½-2¾	3	9	0.5-0.6	0.25-0.3
100,000-200,000	1¾-2	2	8	0.4-0.5	0.15-0.2
200,000-500,000	1¼-1½	1¼	7	0.35-0.4	0.1-0.125
500,000 and up	1-1¼	1	6.5	0.3	0.06-0.08

TABLE 2 Guidelines for Determining Minimum Space Requirements

Population served	Shelving Space*			Reader space, sq ft	Staff work space, sq ft	Estimated additional space needed, sq ft‡	Total floor space, sq ft
	Size of book collection, volumes	Linear feet of shelving†	Amount of floor space, sq ft				
Under 2,499	10,000	1,300	1,000	Min. 400 for 13 seats, at 30 sq ft per reader space	300	300	2,000
2,500-4,999	10,000, plus 3 per capita for pop. over 3,500	1,300. Add 1 ft of shelving for every 8 vols. over 10,000	1,000. Add 1 sq ft for every 10 vols. over 10,000	Min. 500 for 16 seats. Add 5 seats per 1,000 over 3,500 pop. served, at 30 sq ft per reader space	300	700	2,500, or 0.7 sq ft per capita, whichever is greater
5,000-9,999	15,000, plus 2 per capita for pop. over 5,000	1,875. Add 1 ft of shelving for every 8 vols. over 15,000	1,500. Add 1 sq ft for every 10 vols. over 15,000	Min. 700 for 23 seats. Add 4 seats per 1,000 over 5,000 pop. served, at 30 sq ft per reader space	500. Add 150 sq ft for each full-time staff member over 3	1,000	3,500, or 0.7 sq ft per capita, whichever is greater
10,000-24,999	20,000, plus 2 per capita for pop. over 10,000	2,500. Add 1 ft of shelving for every 8 vols. over 20,000	2,000. Add 1 sq ft for every 10 vols. over 20,000	Min. 1,200 for 40 seats. Add 4 seats per 1,000 over 10,000 pop. served, at 30 sq ft per reader space	1,000. Add 150 sq ft for each full-time staff member over 7	1,800	7,000, or 0.7 sq ft per capita, whichever is greater
25,000-49,999	50,000 plus 2 per capita for pop. over 25,000	6,300. Add 1 ft of shelving for every 8 vols. over 50,000	5,000. Add 1 sq ft for every 10 vols. over 50,000	Min. 2,250 for 75 seats. Add 3 seats per 1,000 over 25,000 pop. served, at 30 sq ft per reader space	1,500. Add 150 sq ft for each full-time staff member over 13	5,250	15,000, or 0.6 sq ft per capita, whichever is greater

SOURCE: American Library Association, Subcommittee on Standards for Small Libraries, Public Library Association, Interim Standards for Small Public Libraries: Guidelines Toward Achieving the Goals of Public Library Service (Chicago: The Association, 1962), p. 15. This brief 16-page report is based on standards set forth in ALA's, *Public Library Service; A Guide to Evaluation with Minimum Standards*. It is intended to provide interim standards for libraries serving populations of less than 50,000 until these libraries can meet the standards of ALA's *Public Library Service*.

*Libraries in systems need only to provide shelving for basic collection plus number of books on loan from resource center at any one time.

†A standard library shelf equals 3 lin ft.

‡Space for circulation desk, heating and cooling equipment, multipurpose room, stairways, supplies, toilets, etc., as required by community needs and the program of library services.

LIBRARIES

Space Requirements

and study areas. Arrangements of this type have proved to be most effective in smaller libraries and in branch library buildings.

The following formulas, developed by Joseph L. Wheeler, are based on building analyses made over a period of more than 30 years. If the estimated future population is less than 10,000, allow 10 seats per thousand; if more than 10,000 but less than 35,000, allow 5 seats per thousand; between 35,000 and 100,000, 3 seats per thousand; between 100,000 and 200,000, 2 seats per thousand; between 200,000 and 500,000, allow 1½ seats per thousand; and 500,000 and up, 1 seat per thousand.²

As an established rule of thumb, minimum allowances are made of 30 sq ft per adult reader and 20 sq ft per child. These allocations for reader seating are in terms of net space for readers, chairs, tables, aisles, and service desk. Seating requirements should be listed according to the several areas of the building. In addition, the program statement should estimate the proportion of table seating to informal seating (See Figs. 4 to 6.)

Space for Staff

Space requirements for the staff must also be stated in the program. These estimates will be conditioned by (1) anticipated growth for a 20-year period and (2) the nature and extent of the library's service program. The American Library Association recommends that space for staff be calculated on the basis of "one staff member (full-time or equivalent) . . . for each 2,500 people in the service area."³ It is a minimum standard that includes pages but not maintenance personnel. Although suitable for application to most situations, it must not be regarded as inflexible. As an example, a library that is not affiliated with a system will probably require a somewhat larger staff than libraries that have joined together in cooperative arrangements, such as centralized technical processing centers. Moreover, something as fundamental as the number of hours per week the library is open will affect the size of the staff and, consequently, space requirements. There are striking differences in staff requirements between libraries open 20, 38, or 72 hours per week.

Staff space requirements should be calculated on the basis of 100 sq ft per staff member. It is important that this standard be met for there is ample evidence that space for staff has been outgrown more rapidly than any other type of space in most library buildings. Only too often is it easy to forget that an expanding service program will require the support of an enlarged staff. The unit of measurement of 100 sq ft per staff member includes space for desk, chair, books, and equipment.

A checklist of staff work areas should include (1) administrative offices, (2) work rooms, and (3) staff lunch and lounge rooms.

Administrative offices should include a combination librarian's office-trustee room; spaces for the assistant librarian and a secretary-receptionist; business office; and other related offices. Work room areas should be provided for technical processing; reference, circulation, extension, and other departments; subject specialists; and supply storage. Comfort facilities for the staff should include cooking and lunchroom areas as well as appropriate locker, lounge, and toilet facilities for both men and women. Comfortable working conditions contribute to effective personnel administration as well as to efficient library service.

² Wheeler, *op. cit.*, p. 18; Wheeler and Goldhor, *op. cit.*

³ Public Library Service, *op. cit.*, p. 43.

Meeting Rooms

With the exception of the very smallest libraries, most public libraries should provide some group meeting space, at least one multipurpose meeting room. At the other extreme, a small auditorium and a series of conference rooms may be required. The services proposed by the library together with community needs for facilities of this type will be the final determinants.

Multipurpose rooms meet two general classes of need. First, they can be utilized for children's story hours, discussion groups, staff meetings, and other library-sponsored activities. Second, various community, educational, cultural, and local government groups will make frequent and varied use of a multipurpose room. To be of maximum value, however, the room should be arranged for easy and effective use of audiovisual equipment. In addition, there should be adjacent closet space for storage of blackboards, folding tables, chairs, and related equipment.

Many libraries provide a small "pullman" type kitchen in an area adjoining group meeting rooms. Serious consideration should be given to including this facility since there are many occasions when it is highly appropriate to serve simple refreshments. A kitchen featuring a compact combination stove-sink-refrigerator unit will not cause administrative or maintenance problems provided regulations governing its use are stated clearly. Separate

provisions should be made for staff kitchen and lounge facilities.

Small auditoriums may feature sloping floors along with elaborate lighting, stage, and projection equipment, or they may be austere with major emphasis placed on flexibility. It is recommended that no auditorium ever be included in a library building program statement without first consulting community leaders. Such facilities are expensive to maintain and, as a result, can place an invisible but dangerous strain on the library's budget unless fully justified. Whenever group meeting spaces are provided, it is important that they be located where there can be access for community use without opening the rest of the building. It is customary to allow from 7 to 10 sq ft per seat for meeting room and auditorium seating.

Space for Mechanical Operations

Included within this category are halls, stairways, toilets, elevators and lifts, air ducts, heating and air conditioning equipment, closets, and shops.

Because it is exceedingly easy to underestimate the amount of space required for mechanical operations, it is recommended that the best available technical advice be secured to assure inclusion of an accurate estimate within the program statement. Fortunately, with the development of new construction materials and techniques combined with new concepts in planning, much less space is needed for these

Fig. 4 Minimum clearances for various body positions in library stack areas.

purposes than was formerly the case. It is suggested that an allowance of 20 percent be made for mechanical operations. In comparison, some planners allowed twice as much space not too many years ago. It is of utmost importance that this space requirement not be overlooked. After the amount of space needed has been estimated, it should be added to the total required for the other activities to be provided in the building.

SERVICE AND SPACE RELATIONSHIPS

As a logical extension of the program statement, it is important that the members of the planning team, especially the architect, acquire an understanding of the interrelationships between areas within the library. It is not enough to simply know how much space is needed; it is equally important to determine which element is to be placed where—and why. Toward this end, service and space relationships can be most readily clarified by analyzing all of the activities that take place in the library. This analysis of both public and staff use can be facilitated through preparation of work flow studies.

The central objective for the library planner is to arrange the several elements in a manner which will assure maximum flexibility. Reduced expenses for supervision, personnel, and construction are among the benefits derived from an "open," flexible building.

More specifically, flexibility implies successful, long-time use of the building. The same area may be used for one or more purposes at different times. The amount of space allocated for a certain use may be shrunk or expanded without structural changes. Furniture and equipment are not fixed and may be relocated.

Ideally, all public services should be located on the main floor of a library in the interests of user convenience, economy, and simplification of operation. Where this is impossible, as in the case of libraries in large cities, every effort should be made to visualize the vertical movement of persons and materials. Under any circumstances, a careful study of the flow of traffic and material is basic to the development of successful service and space relationships. Members of the planning team will find it useful to visualize the traffic flow of library users according to age and purpose of their visit to the library from the point of entrance into the building to the time of departure. Another test that will help to clarify space relationships is to trace a book from the placement of its order to the time it is placed on the public shelves and the cards are filed in the card catalog. (See Figs. 7 to 9.)

In addition to locating a maximum number of public services on the main floor, the following points should be kept in mind:

1. Only one complete card catalog should be maintained. It should be located conveniently as near as possible to the reading and reference areas, circulation desk, and the processing department. Department catalogs, a children's catalog, and shelflist and other processing records should be placed in their respective areas as needed.
2. Except for large libraries, there should not be more than one circulation desk. It should be near the main entrance where there will be direct visual control of the movement of both children and adults.
3. There should be a single public entrance within short distance of the circulation desk. Auditoriums and meeting rooms need not be directly accessible from the main entrance.
4. Public toilets, telephones, and display cases should be located where they can be supervised by circulation desk personnel.

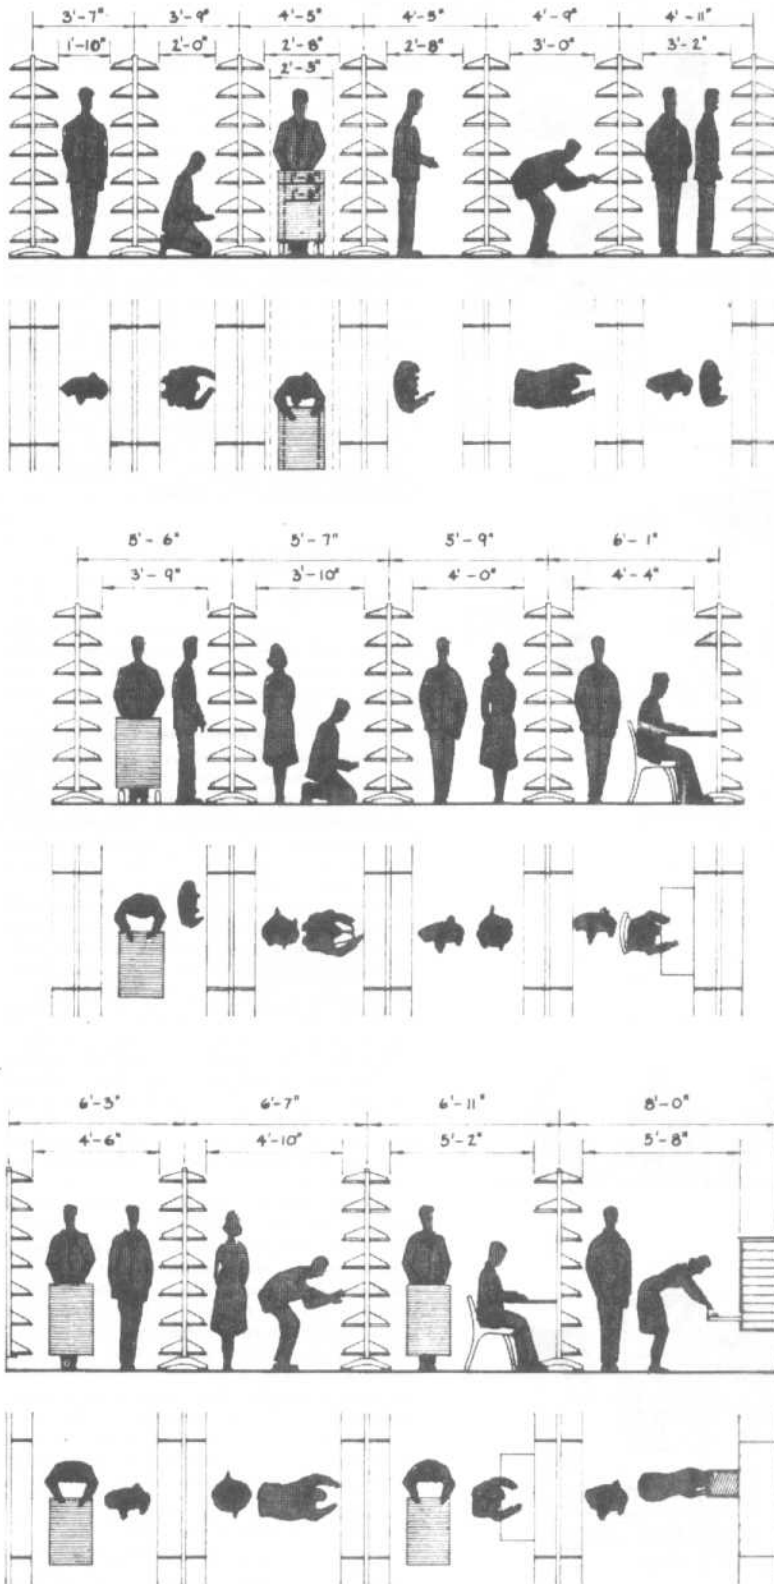

Fig. 4 (cont.) Minimum clearances for various body positions in library stack areas.

⁵Charles M. Mohrhardt and Ralph A. Uveling, "Public Libraries," *Architectural Record*, December, 1952, p. 152.

every new public library, be it the central library or a branch. It is equally true that a site which is located in the heart of a shopping and business district will usually cost far more than a site which is located in a remote or secondary area. Once confronted with the reality of the high cost usually associated with the acquisition of a prime location, there is a tendency toward "instant" compromise. Fortunately, ever increasing numbers of municipal officials, architects, and citizens recognize that the public library cannot fulfill its functions in a second-rate location and that operating costs are proportionately higher for an off-center library than for one which is centrally located. Maximum use is synonymous with lower service-unit costs, and strategically located sites are synonymous with maximum use.

The Site

In addition to central location, several other important criteria should be considered in library site selection:

1. The site should be prominent. A corner site at a busy intersection where the library can easily be seen is preferred. Maximum use should be made of display windows and views of the interior.
2. The site should permit street level entrance. Although a site that slopes to the rear has certain advantages, a level site should be acquired if possible.
3. The site should be large enough for expansion, accessibility for service vehicles and bookmobiles, and a modest amount of landscaping.
4. The site should permit orientation of the front of the building to the north in order to minimize glare from the sun. When this is not possible, orientation to the east is the second choice. However, an otherwise excellent, centrally located site should not be eliminated for lack of appropriate orientation. Modern year around temperature control devices and artificial light can be used effectively to minimize sun exposure problems.
5. Rectangular service areas within a building lend themselves to easy supervision. As a result, a site which is rectangular in shape and permits construction of a rectangular building should be obtained if possible.
6. Ideally, a site should have uniform foundation conditions, either rock or soil. Test borings should be made, preferably before a site is purchased.

Certain other conditions should be met if the community is to be adequately served. First, the library should be located reasonably near adequate automobile parking. Second, parking provisions should be made for bookmobiles, other official library vehicles, and library staff members. Third, automobile access to drive-in service windows should be provided where this feature has been incorporated into the library building design.

Although emphasis has been placed on acquiring a site which would be large enough to permit easy horizontal expansion, it is important to note that under certain conditions purchase of a strategically located smaller site can be justified provided there is enough space to locate primary adult public service areas at street level. Both Norfolk and Dallas acted accordingly when they acquired their choice downtown sites. In both instances, multistory buildings were erected with provision made for vertical expansion.

Where Not to Locate a Library

Despite the overwhelming evidence that can be offered in support of central locations for cen-

Fig. 7 Desirable heights for catalog tray consultation.

Fig. 9 Study for charge desk - maximum usable space from one position or station.

LIBRARIES

Branch Buildings; Bookmobiles

tral libraries and branches in cities both large and small, library planners continue to encounter seemingly plausible arguments from those who believe that libraries should be located in civic or cultural centers, parks, or on sites where avoidance of noise or provision for parking is the major consideration. Usually these misconceptions are held by those who are not qualified to choose a library site.⁶ They do not understand the significance of the library in the daily life of its constituents. Quite to the contrary, they associate the library with a setting of monumental buildings, large landscaped grounds, and quiet, aloof surroundings. Libraries are not mausoleums, they are dynamic educational centers whose services and resources must be easily accessible to the greatest number of potential readers.

Specifically, then, remote locations should be avoided. By definition, "remote" means (either literally or psychologically) to be situated at a distance, out of the way, secluded, separate, not primary. Hence the aloof and inaccessible civic and cultural center fits this definition because it is separated from the daily life of the community and is used principally for attendance at special events. How much more satisfactory it is to be where there are bright lights at night rather than in a civic center where governmental offices close at 5 P.M. and there is little activity at night or on weekends.

The San Francisco Public Library is in a civic center and is a classic example of a poorly located library. Removed from the mainstream of community life, it is flanked by municipal buildings, the civic auditorium, and large landscaped areas. The Carnegie Library of Pittsburgh, which is located in a cultural and educational center, has attempted to overcome its problem of remoteness by establishing lending and business reference branches in the downtown area. Such operations are expensive, unsatisfactory, and would not be necessary if the central library were located downtown.

By the same token, it is almost always a serious mistake to place a library in the geographic or population center of a community. Except in those rare instances where there is coincidence between trade center and geographic or population center, such centers are remote and unrelated to the everyday activities within the life of the community.

Another argument that may be encountered is that the library should be located away from noise. Again, if this point is heeded, it will mean placing the building in a remote location. Fortunately, modern technology has provided acoustical materials, air conditioning, and lighting methods which have completely invalidated this argument.

The argument encountered most often, however, is the one that the library should be placed where there is ample parking space for the library's public. Again, the implication is clear, for if the library is to assume full responsibility for providing enough parking, it will be necessary to locate the building in a secondary location where land is cheap.

Although there are some individuals for whom parking is the main consideration in using the library, numerous surveys have reaffirmed the point of view that a downtown, pedestrian-oriented location in the thick of things is the most important consideration affecting use of the public library. To illustrate, the Knoxville Branch, Carnegie Library of Pittsburgh, is located on the main street of a busy commercial district near banks, post office, liquor and variety stores, and public transportation. Its sister West End Branch, two blocks removed from the neighborhood shopping center, enjoys ample parking facilities in a parklike setting.

The centrally located Knoxville Branch, of course, lends more books for considerably less money than does the West End Branch.

As another comparison, a well-stocked bookmobile will lend many more books at a busy suburban shopping center than will secluded nearby community libraries that offer the very same books *plus* parking, peacefulness, and higher service unit costs!

The parking problem cannot be overlooked. On the other hand, it is a communitywide problem that must be solved by the community rather than by the library alone. In fact, choked highways and overtaxed parking facilities are matters of increasing concern to all governments. Perhaps new concepts in mass transit will help to alleviate parking problems throughout the nation. In the meantime, many libraries have attempted to ease the parking problem through provision of curbside book return boxes. Others are experimenting with drive-in return and "will call" windows, similar to those used by banks for drive-in service.

BRANCH BUILDINGS

Branch libraries usually are established as a result of population growth and community expansion. Generally, it is their purpose to provide books and services which will meet the everyday reading needs of children and adult general readers who live within the local neighborhood. The person who requires more advanced information and special materials will use the collection at the headquarters library.

Although there is a definite trend toward the establishment of larger and fewer branch libraries, there are hundreds of branch libraries which vary widely in both size and responsibility. They range from the small subbranch, open but a few hours each week, to large regional centers which provide a full range of library service.

Branch libraries may be found in busy urban shopping centers and quiet rural communities. Many are housed in their own buildings while others occupy rented quarters. In smaller communities, branch libraries sometimes share space in public buildings planned for joint municipal use.

Whether small or large, rural or urban, owned or rented, branch library buildings should be planned with great care. The object of this planning is a building strategically located for the area which it is to serve. It should be attractive, functional, flexible, and economical to operate. Toward this end, it is essential that a written program statement be prepared for the guidance of the architect. This statement should include objectives, services and their interrelationships, physical requirements, and operational procedures. Physical requirements specify the spaces which will be needed for books, readers, staff, meeting and community service rooms, and other auxiliary spaces.

Of equal or even greater importance is the need for adhering to accepted location and site selection standards. The most functional attractive building can never realize its full potential unless it is located where it will be easily accessible to the largest number of people. The following criteria are suggested as a basis for evaluating sites for a new branch building:

1. A branch library usually should serve a minimum of 25,000 to 30,000 people within a 1- to 1½-mi radius of the branch, subject to topographic conditions.

2. A branch library should be located within reasonable proximity of a residential area so that a sizable number of children and adults will be within walking distance.

3. A branch library should be near an important street or highway intersection, especially

wherever public transportation is available.

4. A branch library should be either within or on the fringe of a major neighborhood or regional shopping center.

5. A branch library should be located where it can be clearly seen.

6. A branch library should provide parking space equal to its interior area if general parking facilities are not available.

Other factors to be considered by the planning team are parking space for bicycles and space for delivery trucks. In certain communities where bicycles are used heavily, it will be necessary to make appropriate provisions. Where the terrain is rugged, the use of bicycles may be limited. Planners must also make allowances for library system delivery and repair vehicles. The latter may be station-wagon types, full-size trucks, or both.

In addition to a highly accessible location, a branch library building should incorporate the same basic building details found in a headquarters or central library building.

1. A branch library should be at street level entrance with as little setback as possible.

2. When space permits, it should be a one-floor plan with all public service at ground level.

3. It should have a minimum number of fixed partitions.

4. A branch library should be planned to permit easy expansion.

5. It should have enough windows on its street frontage so that the books and people within can serve as a living advertisement and constant invitation to use the library.

6. It should not have more than one single control desk, thereby reducing operating costs.

7. It should be air conditioned and adequately illuminated.

8. It should have one multipurpose meeting room available for both library and community purposes if such use is anticipated.

Branch library buildings, as well as central libraries, should be located in the heart of retail shopping districts in order to serve the greatest numbers at the lowest cost, for the more who are served the less each service performed will cost. In other words, there are certain fixed operating costs which pertain wherever the library may be located. With the maximum exposure gained from a good location, unit costs are reduced accordingly.

It can be safely assumed that the most successful branch library will be the one that is based on a carefully stated written program and is located in the thick of things. It is of great importance that the accepted principles of planning and site selection not be overlooked merely because a "small branch" is being planned. To bypass any of these steps in planning is to invite mistakes which might prove to be costly. This holds true for new branches, rented storerooms, leased branch buildings built according to library specifications, and branch facilities incorporated into other public service buildings.

BOOKMOBILES

Because of obvious space restrictions, a bookmobile is a book distribution service which cannot serve as a substitute for a branch library, since there are neither reference nor study facilities. Known to many as "one-room libraries on wheels," bookmobiles have become a widely and enthusiastically accepted form of library service.

Although they are used principally to serve sparsely populated fringe and pocket areas where a full-scale library cannot be justified, they are used often to serve densely populated areas until branch libraries can be planned, financed, and built. As a natural by-product and

⁶Wheeler, *op. cit.*, pp. 3-5.

LIBRARIES

Bookmobiles; Bookstack Data

added benefit deriving from their mobility, bookmobiles pretest the validity of potential branch library locations.

Wherever the bookmobile goes, it is met and used by crowds of book-hungry men, women, and children, who are entitled to the use of a facility which provides maximum safety and comfort. As a result, it is important that bookmobiles be chosen with great care. Following a thorough study of local service requirements, the bookmobile planner should visit and inspect bookmobiles being used by other libraries which have comparable requirements. Major attention should be given to equipment. Shelving, desks, electric power, heat, light, ventilation, air conditioning, chassis, and convenience accessories are items which relate directly to function as well as reader and staff comfort.

Bookmobile size will be determined in part by population to be served, terrain, roads, climate, number of books to be carried, and the amount of work space required by the staff. To illustrate, while a tractor-trailer rig may be most appropriate to serve the densely populated Youngstown area, it would not be feasible for use on the mountain roads of sparsely populated rural New Hampshire.

Another item to be explored is bookmobile storage and service facilities at the headquarters library. When a new library is being planned, adequate provisions should be made for the support of bookmobile service.

Library and other officials responsible for the selection of a bookmobile should be guided by the standards for structural design and equipment as established by the American Library Association.

BOOKSTACK DATA

Unit Stack Weights

Books

25 to 30 lb per cu ft of ranges.

Stack Construction

Quoted as 5, 8, and 8 to 10 lb per cu ft, depending upon the manufacturer.

Deck Framing

2 to 4 lb per sq ft of gross deck area.

Deck Flooring

3-in. reinforced concrete slab, 38 lb per sq ft; 3½-in. reinforced concrete slab, 38 lb per sq ft; gross area, with ¼-in. tile or linoleum covering, 45 lb; flanged steel plate floor, 12 lb per sq ft of gross area; 1½-in. marble or slate, 18 lb per sq ft, aisle area.

Live Loads

Building codes vary, but in general, for column loads, assume 40 lb per sq ft of aisle area for live load and reduce this figure 5 percent for each deck below the top deck.

Bookstack Capacities

Among formulas suggested for use in computing the size of stacks necessary to house a given number of books is the "cubook" method, devised by R. W. Henderson of the New York Public Library.⁷ The cubook is a measurement of stack capacity, defined as the "volume of space required to shelve the average book in the typical library." According to this formula, a single-faced section of stack 3 ft long and 7 ft 6 in. high has the following capacities:

100 cubooks (85 percent octavos, 13 percent quartos, and 2 percent folios)⁸

117 volumes (87 percent octavos and 13 percent quartos)

132 volumes (octavos only)

67 volumes (quartos only)

12 volumes (folios only)

The cubook method makes provision for 10 percent of each shelf to remain unoccupied, since it often is impractical to load shelves to their full visible capacity.

To determine the number of sections required when the number of volumes to be shelved is known, the following formulas are used:

Let N = number of single-faced sections required (1 section = 100 cubooks)

1. For a typical library, when the cubook is considered directly applicable: $N = \text{Vols.} \div 100$

2. For a library made up of octavos and quartos only: $N = \text{Vols.} \div 117$

3. For a library made up of octavos only: $N = \text{Vols.} \div 132.3$

4. For a library made up of quartos only: $N = \text{Vols.} \div 67.5$

5. For a library made up of folios only: $N = \text{Vols.} \div 11.7$

6. For a library made up of various size groups when the ratios are known:

$$N = [\text{Octavos} + (\text{quartos} \times 1.96) + (\text{folios} \times 11.3)] \div 132.3$$

Shelf Size The foregoing formulas indicate the number of sections required but do not cover the number of shelves or the proportion of shelves of each width (8 in., 10 in., or 12 in.). In general, the following shelf data applies:

For folios—thirteen 12-in. shelves per section

TYPICAL STACK LOADING DIAGRAM

For octavos and quartos—usually 7 shelves per section, divided as follows:

85 percent 8-in. shelves

10 percent 10-in. shelves

5 percent 12-in. shelves

Area and Volume Requirements The cubook can be reduced to approximate terms of area and volume requirements for bookstacks, as follows:

11.08 cubooks require 1 sq ft of stack floor area

1.48 cubooks require 1 cu ft of space in a stack

These values can be used as follows:

Required stack floor area = No. cubooks \times 0.090

Required space (cu ft) = No. cubooks \times 0.676

Stack Loads: General Variation of Stack Loads for from One to Twelve Tiers

Tiers	8-in. shelving											
	1	2	3	4	5	6	7	8	9	10	11	12
A	495	2,320	4,120	5,890	7,630	9,340	11,029	12,670	14,290	15,880	17,440	18,970

* To be consistent with cubook method, figures shown should be reduced by 10 percent to avoid overcrowding shelves.

⁷ Library Journal, Nov. 15, 1934; and Jan. 15, 1936.

⁸ According to American Library Association, an octavo is about 8 to 10 in. high; a quarto, 10 to 12 in.; and a folio, over 12 in.

By JO MIELZINER

The twentieth century brought an entirely new attitude toward shaping our theaters. Whereas in the past, a consistent, developing production technique gave rise to a single, if gradually developing theater shape for each period, in the last 60 years several theater shapes have been available for our use. Due partly, no doubt, to nineteenth-century historicism and scholarship, a revival of earlier stage forms sprang up to accompany the mainstream tradition of the proscenium stage. There began to be a multiple choice of theater shapes for plays in the twentieth century—a situation that was unknown in previous times. This movement clearly underscored the tremendous activity in theater arts—the thinking and lack of it—being done by all people involved.

Proscenium Theaters

From the turn of the twentieth century to the present day, the proscenium theater—a direct-line survival of the horseshoe opera house that originated in the Renaissance—has continued as the most generally accepted and widely built theater shape in this country. By definition, a proscenium theater is a shape in which the audience faces the performing area on one side only and sees the performing area through an architectural opening that often has an elaborated architectural frame—although that is not an essential element. The performing area is not always limited by that opening; it can project out a nominal distance into the auditorium in the form of what is called a fore-stage or apron. In essence, this is not an intimate theater shape, since the audience and the actors are each in separate, but connected, interior rooms (see Fig. 1).

At the turn of the century, many American proscenium theaters were outmoded and run down, despite the fact that the theater itself was prosperous. Unlike European theaters of the time, in the United States experiments were hampered by the lack of space, prohibitive

The Shape of Our Theatre, Clarkson N. Potter, Publisher, New York.

Fig. 1 The proscenium shape.

Fig. 2 The typical early-twentieth-century American theater had meager and often inadequate stage and supporting facilities.

labor costs, and the overriding profit motive of the commercial American theater. Very few of these theaters were built with adequate machinery—stage elevators or turntables. Tenants were expected to bring everything with them, including turntables and all lighting equipment. Consequently, early-twentieth-century producing groups dedicated to the new stagecraft and contemporary American playwrights found their theaters woefully inadequate in shape and meager in equipment.

The absentee landlord's profits were not put back into the buildings or into new equipment, particularly stage lighting equipment. Actually, landlords were not absent physically. What was missing was any real love of the arts of the theater; instead they substituted a love of profits. If they were away from their theaters for any length of time, their general managers were on hand to keep a watchful eye on financial operations.

One New York City landlord-builder ordered a theater constructed with as little space as

possible for the stage, the lobby, and between-legroom rows. In one instance the box office was omitted entirely. In spite of the owner's concern over his new theater's capacity to operate on a profitable level, the absence of any professional theater people on the owner's or the architect's staff was responsible for the amazing omission. Only in a last-minute inspection by the owner did this situation reveal itself, and a hastily designed and very cramped box office was quickly put in.

One theater builder in Philadelphia forgot to include dressing rooms and later had them constructed in a separate building across an alley, back of the theater. This little convenience meant that the artist, to get from his dressing room to the stage, had to go down to the basement, literally duck under sewage and steam pipes, and then go up into the other building. All this showed little understanding for the art of the theater—and no respect for its artists (see Fig. 2).

Because of this general situation, it was the

producer, not the theater owner, who was forced to keep up with the times and pay for proper facilities and equipment to install portable dressing rooms backstage. I note these almost unbelievable instances not in the spirit of gossip, but to stress the need for the constant presence of a professional theater expert—not on the outskirts of a projected theater design, but in a position of responsibility.

However, some producer-managers who were clients for their own theater buildings had a real love of theater itself, and an understanding of the latest European stagecraft developments. Among them were the Frohmans, David Belasco, and Florenz Ziegfeld; the latter retained architect-scene designer Joseph Urban to design his own theater. Winthrop Ames, a wealthy amateur of the arts, and a thoroughly professional producer, put up the Century Theater on New York's Central Park West. This 2,000-seat theater was notably ahead of its time, but was soon demolished because no contemporary repertory company could fill it.

If the absentee theater owners had been more knowing, if they had even more materialistic imagination, they would have made the kind of improvement that Billy Rose later made to his Ziegfeld Theatre (since demolished). There he equipped the backstage as well as the auditorium with the latest, most efficient lighting equipment and lighting control systems. Even if motivated solely by financial self-interest, this produced lucrative rentals from his tenants, and also provided presentational potential for the users.

Because the picture frame theaters were badly designed and therefore nearly unusable, they have recently been much downgraded. They were not bad simply because they were old or because they had proscenium forms, but because of their initial poor design. What most of us have forgotten is that the proscenium stage has been for centuries and will remain one of our most useful theater shapes.

A Revival of Ancient Shapes

As early as 1914, a group at Teachers College in New York used the simplest bleachers and seats on four sides of a medium-sized room to create an arena stage. An ancient theater shape, the arena stage was used in the great coliseums and arenas of Greece and Rome—but never specifically for drama. This new usage was the beginning of a revival.

The arena is a theater-in-the-round. The stage is surrounded on all sides by the audience. This arrangement puts the greatest number of the audience in intimate proximity with the performer. Both the audience and actor are in the same room. Others were gradually won

Fig. 3 The arena shape.

Fig. 4 The open-thrust shape.

to this cost-saving stage form which automatically minimizes the expensive, elaborate scenery usually associated with the proscenium tradition. (See Fig. 3.)

The period following World War I was exciting both in Europe and America. Inspired by a fresh approach to writing and the new European expressionistic stage designers and producers—Adolphe Appia in Switzerland, Max

Reinhardt and Leopold Jessner in Germany—our best young playwrights, Eugene O'Neill, Elmer Rice, and John Howard Lawson, helped launch and stimulate a new attitude toward stagecraft in the United States.

Expressionistic scene development in Germany and Russia was also reflected in America. Lee Simonson, Norman Bel Geddes, and Robert Edmond Jones produced designs of dramatic imagination for scenery and stage. However, since they were not in the mainstream of commercial thinking, few of these new stages were actually built.

Conventional Broadway was not the only vital place; community and college playhouses sprang up all over the country. But the time and cost of producing scenery led directors to bypass that traditional problem and to investigate other techniques of stagecraft.

Early in this century, the ancient open-thrust stage, which had been used before the development of the proscenium theatre, was revived by several directors and producers. High costs of proscenium productions, which required elaborate and sometimes complicated scenery as well as high operating costs, led to this revival. Coupled with this was a desire to bring greater intimacy to the theater again. (See Fig. 4.)

The open-thrust stage had experienced an earlier revival in Europe. Davioud and Bourdais' unexecuted 1875 opera house design proposed a stage of extreme thrust, extending 50 ft into the auditorium with seating on three sides. And in the twenties, the Parisian actor-director Jacques Copeau conceived a truly open theater chamber of intimate proportions in his Theatre Vieux Colombier. His open stage had multiple

Fig. 5 The open stage of Jacques Copeau's Vieux Colombier, Paris, had multiple levels and a flexible but permanent architectural set.

levels, a number of entrances and exits, and a flexible architectural set, which was permanent and therefore cost-cutting. Neither of these European theater designs directly influenced American stage designs, however, until the educational theater did so much to spur the revival of the open-thrust stage. (See Fig. 5.)

American educators felt that the proper method of teaching Shakespeare was to permit students to act and to observe performances of his plays on the type of stage for which they were written. Educators often attempted makeshift open-thrust stages in whatever theaters were available to them. Scenery of the proscenium tradition was virtually eliminated in open-thrust stagecraft. And ultimately permanent open-thrust stage theaters were constructed by the producers of Shakespeare festivals for such regional and community groups as those at San Diego, California; Portland, Oregon; and later the Folger Shakespeare Library in Washington, D.C.

A thrust stage must not be confused with extended forestages in proscenium theatres, which utilize techniques of acting, direction, and designing that do not differ from standard proscenium stagecraft. A true thrust stage is a platform extending into an open auditorium in which the audience truly surrounds the stage on three sides. There may be exits in the back of the stage, as well as under the audience through vomitory tunnels. A thrust stage is an area deep and wide enough on which to play a full scene. When an apron or forestage is only an adjunct to a proscenium stage, it should not be considered a thrust stage (see Fig. 6).

Fig. 6 The apron shape.

Thus, by the end of the twenties, theater professionals had a choice of not only the traditional proscenium stage but also the revived open-thrust and the arena stage forms.

Hiatus in Theater Building

The Depression of 1929 brought a virtual end to theater building in the United States until the end of World War II. No commercial theaters were built in major American cities between 1929 and 1950. The sole exception was Rockefeller Center's *Centra Theatre*, built in 1936 and demolished in 1950. In the thirties, only a few colleges and universities had the funds to build modern theaters with stages designed for modern stagecraft and modern repertory requirements.

After World War II, America was ripe for a "cultural explosion." Mid-twentieth-century Americans were more affluent, better traveled,

and more cultivated. There was a new boom in theater construction. The quarter-century hiatus in building, however, had left its mark. A whole generation of architects and designers had been passed by, and the new generation was unschooled in the development of stage design. This ignorance led to rampant confusion in theater design.

Multiple Choice at Midcentury

When theatre building activity was resumed, the proscenium was the only widely known theater shape; therefore it continued to be popular. To make the proscenium more effective for mid-twentieth-century use, new developments were introduced by architects and designers. Electrically operated flying scenery, electronic control systems like those that pre-set positions for stage elevators, and predetermined lighting plans made the designing of theaters as complicated as it made the physical operation simpler. More and more sophisticated attention to good sight lines and seating furthered the continuation of the proscenium tradition.

Clients, on the other hand, sometimes continued a status-seeking reverence for seventeenth- and eighteenth-century European models that could not, in all ways, take advantage of these new techniques. A significant example of this reactionary view was the attitude of the Metropolitan Opera Board of Directors toward commissioning a new opera house in Lincoln Center. I am not criticizing the architects' designs or even their execution. The design was chosen with the conviction that the "Golden Horseshoe" of their old (1882) house was sacrosanct. A sentimental attachment to the past, as well as a lack of sympathy with contemporary design, may well have influenced the Board's decision. But I would suspect that the fear of alienating the few, but financially critical constituents was the dominant factor in their decision.

I am well aware that backstage the mechanical facilities of the new Metropolitan Opera House are up to date and undoubtedly do much to keep down the backbreaking operational overhead.

That they did not attempt to peer into the not-too-distant twenty-first century is understandable. The life-span of contemporary structures—particularly those associated with the performing arts, is shortening so quickly that new theater shapes may serve satisfactorily for only a generation or two. But in delib-

erately choosing a multitiered eighteenth-century horseshoe seating plan, the directors were guilty of a graver error than just inflicting substandard sight lines. That error was the failure to recognize that our twentieth-century visual art forms are not just passing fads, but are deeply dyed in our daily lives, in our means of communication and our social behavior. It seems strange that the impresarios of an art form as abstract as music should allow themselves to close their eyes to even the most universally acceptable visual arts of our mid-century.

Today, only after careful consideration, proper planning and design will the proscenium theater regain its usefulness. A modern proscenium theater need not be rigid in its dimensions—either in width or height. Side panels adjacent to the proscenium can have facilities for openings and side stages. Offstage rooms—right and left, up and down, traps and fly loft—all have to be provided. All these elements lend great flexibility to the Proscenium stage, but also make it more complex and more expensive to build. Basically, the proscenium is one of the most flexible theater shapes because any and all styles of production can be effectively realized. For the director, the problems of sight lines and other questions inherent in proscenium productions are fluid. In stagecraft, particularly lighting and settings, everything from the most stylistic and simple designs to the most elaborate and imaginative settings can take full advantage of this shape. Even a play such as *Hair*, which was first performed on an open stage, was successfully produced on Broadway in a proscenium theater. (See Fig. 7.)

The limitation of this theater shape is that it tends to be less intimate than either the Theater-in-the-round or the open-thrust stage. Yet it also must be remembered that many playwrights want the kind of separation between actor and audience that the proscenium shape gives. On the whole, if I were limited to a single stage form, I would choose a flexible proscenium with an ample forestage.

During the 1950s, labor and material costs again led clients as well as producers and designers to seek new methods of stagecraft. So it was that arena stages or theaters-in-the-round gained wider acceptance as a suitable setting for spoken drama. They were less expensive to build and required virtually no conventional scenery. A strong influence during the theater explosion, the arena stage in Washington, D.C., clearly demonstrates how sophisticated theater-in-the-round can be. De-

Fig. 7 In today's proscenium theater, the width of the proscenium opening can often be varied by adjustable panels.

Fig. 8 The arena stage in Washington, D.C., designed by architect Harry Weese in 1961, is an exemplary modern arena-shaped theater.

signed for Zelda Fichandler in 1961 by Chicago architects Harry Weese & Associates, it is a far cry from the frequently seen, makeshift theaters-in-the-round. Well planned and successful, it is actually a theater-in-the-round, but the principle of an audience surrounding the stage is identical. Here both the architect and the owner worked carefully to meet the needs of the company and to solve the technical problems and limitations of such a theater shape (see Fig. 8).

One built-in limitation of arena stages is applicable to all stages surrounded, or partly surrounded, by the audience: the director must constantly change his axis to prevent one group of viewers from being presented with poorer images than other sections of the audience. Actors, as well as the director, must use entirely different attacks on performance and movement. Lighting is also more difficult in arena staging because of the mandatory economy; however, when handled by an artist, this flexible medium can stress the nonillusionistic approach to a design.

In addition, the ability to vary settings is a limitation, both because architectural forms are impractical, and because elevations on the stage have to be limited in scale. In choosing a repertory for an arena stage company, certain plays—such as the classical plays of Sophocles, Euripides, Shakespeare, Molière, and Sheridan—succeed while, on the other hand, some plays written for the proscenium stage must be omitted.

One of the primary advantages of an arena theater is intimacy. Even with 1,000 seats, the most distant member of the audience need not

be much more than 32 ft from the nearest part of the stage. Although in more sophisticated theaters-in-the-round, it is possible to use traps and to fly elements overhead from a modified grid above the center of the stage, scenic investiture is ordinarily reduced to only the most expressive and economical forms of lighting and projection, costumes, props, and simple portable scenic elements that do not mask the actor from any part of the surrounding audience. On the whole, I think the advantages far outweigh the disadvantages of arena theaters. The fact that presentation style stresses imagination and simplicity is surely a strong argument.

Throughout the fifties and sixties a major innovative force in theater architecture has been Irish theater director Sir Tyrone Guthrie. In the fifties, after much acclaimed experimentation in England and Scotland, Guthrie was invited by the bright, ambitious young community leaders of Stratford, Ontario, to establish a theater. Intended primarily for the classics, the theater was first set up inside a tent, and later rebuilt under a permanent architectural structure (see Fig. 9).

Tyrone Guthrie's concept for Stratford, which was worked out with theater designer Tanya Moisewitsch, was appropriately a classical one. The auditorium is based on a steeply banked, semicircular, Greco-Roman, three-sided seating arrangement; it surrounds an open-thrust stage that has many basic elements of the Elizabethan stage. Besides entrances from the rear wall, Guthrie also used vomitories, which are entrances and exits to the stage from below the audience seating areas.

Little if any background scenery is used. Stress is on costumes, props, and lighting, which the director/designer team use in the most imaginative and simplest way to create scenic atmosphere. Light is used almost entirely as illumination, with very little sophistication in movement, color, or image projection. On the other hand, their sophisticated use of costumes and properties has been extremely important in creating a sense of mood and character. The impact of the theater was international. It was intimate and vital, and extremely suitable for the classics.

A few years later, after the Ontario theater had been built, Guthrie himself initiated, with Oliver Rea, a similar venture in Minneapolis, Minnesota. There, he planned with architect Ralph Rapson a variation on the Stratford, Ontario, theater. Corrections were made, for example, in the sight lines at extreme left and right. He included facilities for hanging scenery behind the thrust. It is a token proscenium behind the thrust stage. This combination of the two theater forms was a major innovation. And thoughtful architects and designers throughout the country and abroad studied it with great interest.

An open-thrust stage can be extremely simple, like Tyrone Guthrie's Stratford, Ontario, theater. It can then be elaborated by planning an adaptable grid for lights, props, and scenic elements to be hung directly over the thrust. Yet all this fits into the basically simple staging that is germane to the shape.

The advantages of thrust are clear and strong, but so are its disadvantages. Of the advantages, the greatest is perhaps the heightened sense of involvement gained by both the audience and the actor. Intimacy naturally is enhanced; the movement and pace of the play are swift; and the technique is fluid and cinematographic. The open-thrust stage does, however, diminish the significance of the "illusionistic" style of stage design. (Depending on one's point of view, admittedly, this may be counted either as one of its advantages or as one of its limitations. For me, illusion is one of the lesser achievements of the contemporary theater.) The open stage requires a totally different approach. The cast cannot be directed to act only toward the front, because the audience is on the sides as well. And, in a sense, they must act dimensionally within a scenic scheme, rather than in front of it. Costumes also become more important as do the few but choice properties with which the actors work. And finally, because background pictures are not being created, lighting must become a living element through which players move.

Generally, the open-thrust stage is more flexible than the arena. With the open-thrust stage, the director does not have to worry so much about the actor's back being to the audience. But because the open-thrust is more complicated to design, it may turn out to be more expensive to build than the arena or proscenium theatre.

Perhaps the most outstanding disadvantage is that the more realistic a play is, the less effective it may be for the open-thrust stage. Shakespearean plays and other earlier classics are easily adaptable since in their writing and production they were presented on open Elizabethan stages with a minimum of scenic effects. Much of nineteenth-century drama is considered ill-suited for the open-thrust stage; but this also presents an opportunity for an imaginative director to approach these plays with a radically fresh style.

Of the multiple choices in theater shapes at midcentury, then, three were prominent—proscenium, arena, and open-thrust; but more involved, complex choices of theater shapes were

Fig. 9 The Stratford, Ontario, Shakespeare Festival Theatre has been an influential interpretation of the open-thrust stage. It combines an Elizabethan stage with a Greco-Roman audience seating plan.

yet to confuse the decision-making and design processes of architects and clients.

MULTICHOICE IN A SINGLE THEATER

Besides the choice among three traditional, historical theater shapes, which are available to theater planners and designers today, a new combination of multiples has appeared. Now, we can attempt to have several, or all three of these stage forms in a single building—even in the same auditorium. This unique possibility has led to the extreme complication of present-day theater design and to the utter confusion of present-day theater designers.

The educator's desire to perform Shakespearean plays in the original setting has been extended to a desire also to perform eighteenth- and nineteenth-century plays in the theaters for which they were originally produced. Not content with an open-thrust stage theater for plays written for that basic shape, from the days of classical Greece to the Middle Ages, producers also want a proscenium theater, in which to present Renaissance and later plays. This desire has now spread from the educators to the producers of community and regional theater as well.

Where sufficient funds are available, the building of two theaters—one proscenium and one open—splendidly accommodates this desire. (It must be remembered that in no age but our own were plays written expressly for arena theaters.) However, sufficient funds do not always seem available for such a splendid solution. As a compromise, and it must immediately be recognized as that, architects,

Fig. 10 The total theater scheme, designed by Walter Gropius in 1929, is a chimera holding forth the illusive promise of a multiform stage. It could be changed from (a) the proscenium shape to (b) the open-thrust shape, and (c) the arena shape.

stage engineers, and designers have attempted to build, within a single theater, multi-form stages, which can be changed from one shape to another (Fig. 10).

The Multi-form Stage

Inspired by the total theater scheme of the late architect Walter Gropius, which was designed in 1929, but never executed, engineers have attempted tour-de-force theaters that could be altered from proscenium stage arrangements to open-thrust stage arrangements—and even to the arena shape. Engineering and mechanical ingenuity, coupled with accurate electric controls, have made these chimeras appear attainable. It is my feeling, however, that this concept has never been successfully realized.

Multi-form stages were developed for clients who felt they could afford to build only one theater, but were unable to commit themselves to a single stage form. The mechanical multi-form stage was also intended to make flexible space operational for theaters of large size, and to save manpower and time in rearranging stage form and audience seating plans.

In Fig. 11 I have illustrated one theater interior that can be used for two types of stage productions by rearranging some of the seating and changing the proscenium proportions. The first is a true proscenium technique. Then, by using an elevator to bring up a thrust stage and readjust the seating elements, this same theater can be used for a second technique—the open-thrust stage.

At the Loeb Drama Center at Harvard University, mechanical means have been provided to create three entirely different relations between acting area and audience seating. De-

signed by architect Hugh Stubbins and theater engineer George Izenour, the Loeb Theatre interior itself does not essentially change—only the mobile units within its walls and under its ceilings. The avowed purpose of this highly selective and mechanical complex was to satisfy the needs of student directors, actors, and authors to create any and all stage shapes at will (see Fig. 12).

For all multi-form stages, there is a price paid—not only in dollars, but also in sacrifice of function. No multi-form stage can be either a perfect thrust or a perfect proscenium stage. Yes, they work. But the additional expense, both in design and construction and ultimately in operational costs, is not worth the loss of unified purpose that characterizes a theater with a single stage shape. Such experiments fail basically for the very reason that in none of their two or three or five alternate adjustments has one a feeling of a well-designed, simple, clean, direct, single-form theater. In order to make a collective multi-form that works at all, each single arrangement must be a compromise.

It has been my experience that impressive and technically practical as some of the experiments may be, in none of their various chameleon-like changes are they as effective in either arrangements or elements as the stages designed for a specific purpose.

Even a theater that can be changed to create only two of the basic stage shapes is a compromise. But such dual-form or "hybrid" theaters appeal to clients who desire some of the advantages of the thrust stage and, with a minimum of changeover, the use of the same auditorium as a proscenium stage. And it must be admitted that a stage that can be changed from

arena shape to open-thrust shape may not be so serious a compromise. The real difficulty is in designing a theater that will accommodate both the axial vision demanded by the proscenium stage and the radial vision that is basic to the open-thrust stage.

I have been involved (although after instinctive personal protest) in designing a number of dual-form theaters. An honest architect or designer must hold a Monday-morning quarterback session with himself, if not in public, upon the completion of an important job. I feel that a public session here will provide a valuable share of my experience.

It was tragic that one of the great architects with a true and sensitive understanding of theater, the late Eero Saarinen, should have lived to complete only the Beaumont Theater of Lincoln Center. It was a privilege to be code-signer with him on the stage and auditorium. When Eero and I were given the responsibility for designing the two theaters for the Lincoln Center Repertory Company, we met privately for long, honest studies. I found, to my pleasure, that our basic concepts were in agreement. First, neither of us believed in anything but single-form stages; we both were completely opposed to a multi-form stage. If our original proposition had been accepted, we would have had the upstairs theater slightly smaller and the downstairs theaters slightly larger. One of them would have been pure thrust stage and the other pure proscenium. The question of which form would be which size would have been left to the building committee. That is, if the committee voted that the larger theater should have a proscenium stage, we wanted that theater to be a pure proscenium theater, in the best sense, and the other to be a pure open-thrust stage—and vice versa. (See Fig. 13.)

We were overruled. In fact, some members of the committee even talked about a basic multi-use scheme for the Beaumont. We turned that down completely, but we realized that we would have to accept the compromise of a dual-form design. Our original proposition would have been the wiser decision, and ultimately far cheaper in both initial costs and in subsequent operating costs.

However, Lincoln Center gave us months of exploratory time and supported the costs of experimental designs and models which were shown to the building committee of the Repertory Company and to a group of theater critics. A small, but very volatile minority of them supported the idea that the open-thrust stage should be the dominant form. But at the end of the investigation, the consensus was that we should design the larger theater so that it could be used as a proscenium theater and as an open-thrust stage; and that we, as designers, should find some practical means of making the changeover relatively simple.

We pointed out that to meet the production schedule of a repertory company for a two-hour changeover between matinee and evening, it would be imperative to install expensive automatic mechanical equipment. For example, if a production using open-thrust was completed at 5 or 5:30 and the evening schedule called for proscenium staging, an enormous amount of work would be required not only in changing the scenery and lighting, but in changing the seating plan and the open-thrust stage itself. What we designed at the Beaumont Theater for this changeover can be effected in 2 hours.

It is achieved by locating the front group of seats on a large lift that descends to the sub-basement where a turntable rotates them, substituting an open-thrust stage, which is then raised into position. Proscenium panels at the Beaumont can be opened to make a maximum

Fig. 11

(a)

(b)

proscenium opening that is 50 ft across. When the thrust is in use, the panels are completely closed; then actors can enter from right and left downstage of the proscenium panels and from two vomitory entrances under the front orchestra seats.

It must be stated categorically that multi-form stages are designed for dramatic productions of plays only. In the case of the Beaumont, the acoustical characteristics are specifically for the spoken word. The theater cannot be used successfully for opera or musical recitals.

Multiuse Auditoriums

An approach to theater shapes born of the mid-twentieth-century electronic era, and perhaps twentieth-century indecision, is the multi-use auditorium. It is an attempt to satisfy the client who wants an auditorium so adaptable in relationships that any and all the performing arts can be accommodated. Not only do performing groups want a theater to house plays, but they also hope to use their new auditoriums for opera and musical productions, concerts, and recitals. But music reverberation time demands a greater spatial volume than that for the spoken word. What results is an attempt to build one hall that can be suited to both music and drama by altering the very volume of the auditorium. This implies large-scale physical changes being made to ceiling elements and even to the side walls of the auditorium. In some instances, an entire balcony can be shut off for the purpose of changing acoustical characteristics and audience capacity.

Colleges and universities have led the race in building such facilities. High schools have built structures that attempt to accommodate the basketball court, as well as the performance of Ibsen and the choral society recital. Combinations such as the gymnasium and the cafeteria have been tried as a means of saving

(c)

Fig. 12 The Loeb Drama Center at Harvard University, designed by architect Hugh Stubbins and theater engineer George Izenour in 1960, is a small-scale realization of the multi-form stage. Electrically operated mobile seating units and stage sections can be rearranged to create (a) a basic proscenium shape, (b) a basic open-thrust shape, and (c) a modified arena or center stage shape.

space and construction funds. Such schemes appealed equally to builders, architects, and engineers, as well as clients. The multi-use theater thus spread to fantastic degrees. And it has become a byword of confusion in the 1960s. Not only the idea but the definition of the words "multi-use" or "multipurpose" have become confused, even by theater experts.

It is understandable that members of boards of trustees or college regents cried out for a single design to meet all the needs of all the performing arts. Even in affluent times, it is not easy for a large university or regional theater group to raise enough money to build more than one good theater. And there will inevitably be an avid army of architects, engineers, and acoustical specialists willing to take on that challenging desire of clients to accommodate all the performing arts in a single auditorium. Even when the architects or consultants are men of integrity and theater experience, they may find difficulty in persuading building committees that however well an auditorium may suit the combined needs of the choral society and the music school opera, it cannot possibly be used for intimate drama as well.

This is when the dangerous plea is made to bring in the engineering magic that we see in so many regional and college theaters today, and in such community auditoriums as the Jesse Jones Hall in Houston.

During the 1960s, engineering firms devised astounding mechanical systems that changed the very shape of an auditorium, pitched the floor, tipping the ceiling and cutting off the balconies, pivoted the walls, and rolled banks of seating across the floor and stage. In too many of these cases, these electronic tails wagged the theatrical dogs.

Not all engineering developments were futile, however. Certainly in terms of stagecraft, electronic controls for rigging and lighting systems, which were often developed for such auditoriums, have been astonishing in their programs of complicated presentational problems, but these are mechanical contributions to the backstage area and are not to be confused with the mechanical manipulation of the architectural front-of-the-house arrangements.

It is certainly human on the part of an owner or manager to feel that a single auditorium with adjustable elements serves in place of what might otherwise be a complex of two or three separate theaters. But every medium in the dramatic and musical arts cries for a specific scale for the performing area and the audience. With the spoken word in drama, the sense of intimacy is essential both visually and aurally. Add music and singing from a musical comedy, and the scale of the auditorium can increase appreciably.

An auditorium that is good for the actor's voice is technically ineffectual for the singing voice and for musical instruments. The reverse is equally true. On an everyday level, we know that when we want to say something intimate to a friend, we do not shout it across a courtyard. We approach closely, eye to eye, and speak quietly in close contact, as in intimate drama. If we want to sing an aria to that same friend, we would back away or choose a room of sufficient size. The same principle holds in choosing a theater shape.

Specifically, the distance between the last viewer and the performer can increase because when acting is augmented by broader techniques, the audience can be much farther away from the performer and still enjoy an acceptable contact. From operetta to grand opera, an even greater change in scale is acceptable. In fact, the patron who enjoys second-row-center seats at a drama would find grand opera completely unacceptable at

Fig. 13 The Beaumont Theater at Lincoln Center, designed by Eero Saarinen and Jo Mielziner in 1960, can change its shape from (a) an open-thrust stage to (b) a proscenium stage with a modified apron.

this close range. To many followers of opera, of course, the aural appreciation is almost complete without the visual.

The scale that I have been referring to is not only the distance between the audience and the forestage but also the width of the playing stage or proscenium opening. As an example, a good width for a legitimate play is not much more than 35 ft; whereas opera stages will open 60 to 80 ft in width.

It is self-evident that the solution to housing all these art forms in one building must be a magic one, if technically successful. Furthermore, this technical magic must be a dominant part of the basic design. The multi-use auditorium is one of the most serious mistakes in the history of theater design. The notion that

any single design can be used for all purposes is nonsense.

Uncommitted Theater Spaces

Still another theater design approach that developed during this period of "theater explosion" is one for which there is no historical precedent in the tradition of our indoor theaters. It is based on the idea that neither of the basic elements that make up a theater—audience or stage—should be predetermined so far as their location or configuration within the theater are concerned.

In effect, this concept says that within the space provided by the architect, an undetermined stage area and seating area may be set

Fig. 13 (cont.) The Beaumont Theater at Lincoln Center. (c) The section shows a very deep stage planned for a repertory schedule. The deep stage, combined with large stage wagons, and a "saturation lighting" system as well as the multifunction stage mechanism make it possible to change stage shapes and scenery from production to production in a matter of hours with minimum labor.

at will in a wide variety of relationships, arrangements, and relocations. This final theater concept goes one step further than the mechanized theaters. It rejects any and all means for creating a specific playing area or an audience area. Its proponents say, "Give me a cocoon that shuts out the outer world, and in it we will create our concepts without the aid of predetermined form." They feel that it frees future theater users from any "set interior arrangement." They also proffer what they feel is the advantage of a simultaneous and multiple approach to dramatic problems. Theirs is the "uncommitted theater space."

Back in the 1890s, the great scenic artist Adolphe Appia said, "Let us abandon theaters to their dying past, and let us erect simple buildings instead, merely to cover the space where we work—no stage, no amphitheatre, only a bare and empty room." This bold pronouncement, like many manifestos, bears some analysis. Any serious student of the theater who admires Adolphe Appia's magnificently conceived stage settings knows, however, that to achieve the subtlety of his mood lighting and the perfectly proportioned grandeur of his plastic forms, the most complex and technically sophisticated equipment must be available. Much of this equipment must be located not only backstage but in the auditorium itself and subtly related to the stage area. In other words, Appia's "bare empty room," once equipped to meet the high standards of his production concepts, would lose all semblance of nudity and emptiness and might become a well-conceived and carefully predetermined theater.

The limitations of mechanized multifunction schemes are even greater in these uncommitted theater spaces. On the economic side, the budget for such an indeterminate theater must be greatly increased for purely mechanical equipment, if for no other. In order to justify the alleged freedom, a maximum amount of mechanical support must be available in every corner of the uncommitted area. Naturally egresses and exits, ventilating and heating equipment, supporting technical elements and power outlets for lighting must be predetermined and fixed. And the operating costs for moving this equipment are major restrictions on the alleged freedom.

Any rational study of the intricate problems relating to sight lines, acoustics, or lighting

must also lead one to the conclusion that to keep these relationships in an undetermined plan can mean only that the ultimate quality of any single interior relationship is bound to be below par.

The only logical justification for this non-mechanical, multifunction approach is for a university that offers a course in theater architecture. As a really effective working laboratory for the study of acting, direction, and stage design, it is one to be researched and explored.

Uncommitted Spaces for Involvement?

Another current trend in stagecraft is the desire for even further involvement of the actor and audience. I refer to a greater psychological and physical contact between audience and actor, and to a greater use of sensory as well as visual involvement throughout the theater. It has been suggested that the uncommitted theater space fosters this involvement.

Ever since the 1900s, nonobjective and totally abstract experiments in the arts have been expressed beyond the painter's and sculptor's studio. Changes in all communication arts—written and visual—have influenced dramatists in a revolutionary way. Poetry, prose, and journalism have all been affected by the tempo of the radio, recorded music, and their extension into cinematography and television. Poets have rejected rhyme, meter, and syntax. Prose writers have made equally insurrectionary demands on their medium. In the first 50 years of this century the theater reflected very little of this movement. In recent years, avant-garde writers and directors have plunged into radical experiments in what they felt was a new theater-oriented field that furthers audience involvement.

When I refer to total involvement, I do not mean what is currently referred to as a "Happening." The talk about Happenings is based on a valuable instinct—the genuine desire for greater contact, for greater participation of both audience and actor, but it is practiced and preached in an undisciplined and, I think, uncreative way. It is undisciplined because it makes a point of the fact that there is ostensibly no premeditated play, no rehearsal, no restrictive texts.

Although the charade, the conversation, the story, and the extemporaneous narrative have

value, they are not basically theater. Any theater form—like all serious art forms—is born of deliberation, self-discipline, and creativity. To rely on improvisation, no matter how talented the actor, or how receptive the audience, is to misunderstand freedom.

Freedom in art is not license. The artist can be free only if he masters and accepts the limitation of his medium. I have always believed that authors and directors must be given the greatest freedom in staging. In the auditorium and on the stage, the greatest range of lighting, scenic equipment, and spatial freedom must be available. If a new play needs one hundred different visual indications of mood and background, it must be provided.

I have worked with directors and authors who desperately wanted to be free of any set format. But gradually, to have effects, lights, and scenic elements meet the needs of an actor at a precise moment, we started to reintroduce a theatrical limitation—dramatic form.

Similarly, we must accept and work with the physical limitations of our stages. If I have a stage that is only 10 ft deep, and I want to give the impression of unlimited space, I accept that 10 ft and do something with it. Suggestions and implications, whether they are visual, oral, or aural, are means of working with one's limitations. It might be the use of the magic of poetry or of music's abstract sounds. The power of the creative artist is infinite, but only when he masters the technique in which he creates. Yet all these production aids, these minute details, must be made practical and must be carefully timed and rehearsed. All the environmental background, born in excitement and high imagination, must be transposed into controlled and disciplined technique.

I feel I must state that I am not, on principle, anti-Happening. It must be said on behalf of Happenings that they do accentuate some of the better trends fostered by all contemporary dramatists and stage directors. They have one outstanding characteristic in common with other modern theater movements—the desire to accentuate actor-spectator relationships.

The advocates of Happenings question the accepted concepts of actor-audience spatial relationships. Michael Kirby states in the *Tulane Drama Review* (Vol. 10, No. 2, p. 40, Winter, 1965):

Performance and audience are both necessary to have theatre. But it might be thought that it is this very separation of spectator and work which is responsible for an "artificiality" of the form, and many Happenings and related pieces have attempted to "break down" the barrier between presentation and spectator and to make the passive viewer a more active participant. At any rate, works have recently been conceived which, since they are to be performed without an audience—a totally original and unprecedented development in the art—might be called "activities."

It would be pointless at this early stage of the avant-garde experiments in Happenings even to suggest what formalized theater shape they might take, or if they will have any influence at all on theater shapes. Their most vocal leaders seem to disagree about the best environment in which this new and exotic hybrid will flourish.

At this writing, this theater of protest does find what seems to be adequate housing in a large variety of structures—both in and out of the theater. So varied are they, that this particular form of dramatic expression does not easily fit into this discussion of theater shapes. If and when it matures into a new art form, then it may develop a stage and auditorium especially designed for its own needs. I doubt that it will be a totally uncommitted theater space.

THEATERS

Sight Lines

By HAROLD BURRIS-MEYER and F. G. COLE

SIGHT LINES

If the patron is to see satisfactorily, plan and section must conform to a number of limitations which are set forth in the following list. To design an auditorium is to determine a seating area within these limitations and to establish position (not shape) of walls and shape of floors therefrom.

1. The horizontal angle of polychromatic vision (no eye movement) is approximately 40° .

2. The horizontal angle to the center line at which objects onstage, upstage of the curtain line, cease to bear the intended relationship to other objects onstage and to the background is approximately 60° .

3. The horizontal angle to a flat projection sheet at which distortion on the screen becomes substantially intolerable is 60° measured to the far side of the projected image. Curvature introduced into the screen may render the distortion less from the extreme seats on the opposite side of the center line of the house but will increase distortion from the seats on the same side of the center line (see Fig. 14).

4. Judged by the audience's ability to recognize shapes, and confirmed by free audience choice of seats, the following is the order of desirability of locations:

- front center (except when the screen is close to the front row)
- middle center
- middle side
- front side
- rear center
- rear side

5. Audiences will not choose locations beyond a line approximately 100° to the curtain at the side of the proscenium.

6. The vertical angle beyond which ability to recognize standard shapes falls off very rapidly is approximately 30° (see Figs. 15 and 16).

7. The recommended maximum angle of motion picture projection to the horizontal is 12° .

PLAN

If the foregoing limitations are applied in the horizontal plane for any given proscenium opening, they will limit an area of maximum value as seating space which is approximately elliptical. It is interesting to note that this shape for an auditorium plan was pioneered by the late Joseph Urban who had little of the present data to work with and may safely be assumed to have chosen the shape largely on esthetic grounds. A fan shape provides additional seating space at minimum sacrifice of sight lines, but nobody wants the seats in the extreme rear corners.

Seating

Occupants of all seats are visually related to the performance when the seats are oriented toward the stage. This necessitates curving the rows of seats. The center of curvature is lo-

cated on the center line of the auditorium approximately the depth of the house behind the proscenium. Budgetary limitations may dictate that seats be in straight rows to simplify construction; these rows can at least be related to the center of attention on stage by being placed on chords of the optimum row curvature.

Stagger

To provide best visibility from any seat, no patron should sit exactly in front of any other

patron unless more than one row distant. This requirement makes it necessary to stagger seats. Staggering is accomplished by the non-uniform placement of seats of varying widths in succeeding rows. Unless the walls of the theatre are parallel (which is acoustically hazardous), it is extremely unlikely that more than a very few rows can be made up of seats of uniform width. The lack of uniformity thereby introduced provides the means by which staggering can be accomplished. Seats are made with uniform standards and interchangeable backs and seats so that a wide variation of seat width is possible; a variation from seat to seat of an inch or two, cumulative enough to accomplish satisfactory stagger and make rows even, is not noticed by the patron.

Various seating companies have their own schemes and formulas for seat stagger, some of them patented. The client may ask a seating company for a seating plan and should examine it critically for (1) insufficient stagger in occasional areas of the house and (2) the introduction of seats narrower than the acceptable minimum.

Aisles

Aisles are of questionable desirability except in the largest houses. They must, however, be employed in many localities because of building laws which make no provision for continuous-row or so-called continental seating in which all rows are widely spaced and serve as transverse aisles. Many a bad sight line has resulted from putting the maximum legal number of seats, usually 14, into each row in every section. Obviously, for purposes of seeing, radial aisles are best, with curved aisles only slightly less efficient. Aisles perpendicular to the curtain line often have the accidental result of making side section seats undesirable because people using the aisles interrupt the view toward the stage. The box office would

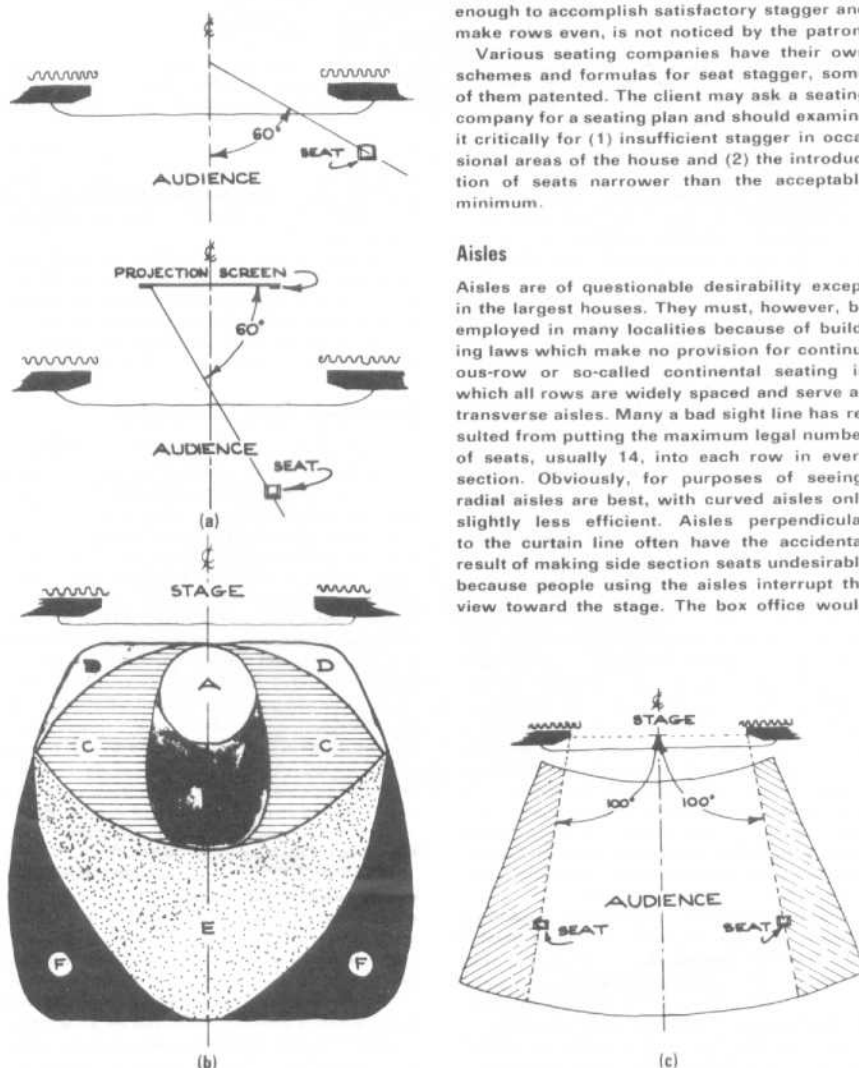

Fig. 14 (a) The horizontal angle to the center line at which objects onstage, upstage of the curtain line, cease to bear the intended relationship to other objects onstage and to the background is approximately 60° . The horizontal angle to the projection screen at which distortion on the screen becomes substantially intolerable is 60° . (b) Based on the ability to recognize shapes and confirmed by sequential seat selection of unreserved seats, the order of desirability of locations is: A, front center, except when the picture screen is close to the front row; B, middle center; C, middle side; D, front side; E, rear center; F, rear side. (c) Audiences will not choose locations beyond a line approximately 100° to the curtain at the proscenium. The shaded areas contain undesirable seats.

Fig. 15 The vertical angle above which ability to recognize familiar shapes falls off very rapidly is 30° .

like a theatre with all seats in the center section. A center aisle wastes the most desirable seating area in the theater and inevitably causes the objectionable condition of seats near the aisle being directly in front of each other. (See Fig. 17.)

Depth of House

There are many formulas used to determine the depth of the house, or more accurately, to determine the relationship between depth of house, width of house, and width of screen or proscenium. They vary considerably and are all empirically derived on the basis of existing theaters, with too little reference to whether such theaters are good or not. Typical are the following: Optimum depth equals 4 times screen width. Maximum depth equals 6 times screen width. Depth equals 1.25 to 2.35 times

house width when house width is 2.5 to 3.5 times screen width. Practically, there are only two significant considerations in planning the depth of the house:

1. Visual acuity. Normal human vision can perceive a minimum dimension or separation equal to 1 minute of visual arc. Translated into space measurement this means that at 10 ft a normal eye can perceive a dimension of 0.035 in., at 50 ft, 0.175 in., and at 100 ft, 0.35 in. Details of actors' make-up and facial expression are not plainly recognizable at distances of more than 50 ft from the stage.

2. Capacity. The larger the house, the lower can be the price per seat or the greater the gross. If the box office is not to be considered, capacity may be limited by optimum seeing requirements, and the last rows kept within 50 ft of the stage. As various requirements

Fig. 17 Straight radial aisles are better than aisles which curve or bend.

operate to increase capacity, the distance of the rear seats from the stage must be increased and seeing conditions impaired in proportion. The theater operator may compensate the occupants of these seats by charging less for them. For shows involving live human actors, 75 ft is generally accepted on grounds of visibility as maximum house depth. (See Fig. 18.)

In theatrical entertainment which has as its chief visual component human actors (live shows), the degree to which these performers must be seen to satisfy the audience and put the show across varies.

A. Details of facial expression and small gesture are important in legitimate drama, vaudeville and burlesque, intimate revue and cabaret.

B. Broad gesture by single individuals is important in grand opera presentation, musical comedy, and the dance.

C. Gesture by individuals is unimportant and movement of individuals from place to place is the smallest significant movement in pageant.

It follows then that theaters planned for the types of entertainment listed under A must be limited in depth of auditorium so that visibility from the remotest seat still allows the occupant to perceive facial expressions (not over 75 ft).

Theaters planned for the types listed under B may have greater distance from the stage to the remotest seat, but this distance is set at a maximum beyond which the individual actor is diminished to insignificance (approximately 125 ft).

Spectators in the last rows at the Radio City Music Hall in New York, looking through a distance ranging from 160 to over 200 ft, depending on the location of the performers onstage, see a ballet reduced to the size of midgets, and an individual performer, even with the dramatic enhancement of a follow spot, is a very insignificant figure indeed.

Fig. 18 Location of center of curvature for rows of seats.

Summary

Given the proscenium opening and capacity, laying out the orchestra and balcony or balconies in plan becomes a simple and straightforward process. Sight lines determine proscenium splay and house width. Visibility limits and capacity determine depth. Minimum distance from stage or screen to first row is determined in the section.

As can be realized from the foregoing requirements for seeing, any scheme which attempts to provide flexible audience-performance relationships sacrifices something, usually in every form attempted. The multifunction theater cannot be justified except as a laboratory, where certain limitations are an acceptable price for flexibility and the box office does not need to support the enterprise.

SECTION

The vertical angle of 30° at the spectator's position establishes the distance from the closest seat to the screen or to the highest significant object on the stage. The lowest seat in the orchestra must be located where the patron can just see the stage floor (except in the case of theaters built for motion pictures only). The highest seat in the balcony must be on a line which is not more than 30° to the horizontal at the front curtain at the stage floor if it is not to be above the limit of reasonable distortion. The standing patron at the back of the orchestra must be able to see the top of the screen, which is usually as high as any significant portion of a stage setting. Each spectator must see the whole stage or screen over the heads of those in front of him. Within these limits the floor slope of orchestra and balcony can be laid out: the first step in determining auditorium section. (See Fig. 19.)

Several methods have been offered heretofore for developing the floor slope. Doubtless others will be offered in the future. The authors present the following method as one which assures unobstructed vision from all seats. It may be noted that this system produces a floor slope considerably steeper than that in many existing theaters. It also produces better seeing conditions.

To determine floor slope, establish eye position of spectator in first row on center line by approximately 30° vertical angle above. For live shows, stage floor will be approximately 2

Fig. 16 (a) A scene of direct conflict loses its visual significance to spectators outside the angles D_1-D-D_1 , etc. One performer covers the other for spectators inside the angles D_1-D-D_1 . (b) Scenes of direct conflict staged anywhere between B and C on an extended stage retain visual significance for all spectators between lines BB_1 and CC_1 .

Cultural

THEATERS

Sight Lines

in. below this level. For theaters designed solely for motion pictures, the location of the stage floor is not critical; the position of the bottom of the screen is. (See Fig. 20.)

A point 3 ft 8 in. below, and 18 in. in front of the eye position will be the floor level for the front row. (1) Draw a sight line from the eye position to downstage edge of stage, and extend it back of the eye position for the front row, step off horizontal seat spacing (back to back), and draw vertical lines at the points thus established. (2) Establish a point 5 in. above the intersection of the extended sight line and the next vertical line. (3) This is the eye position for the second row and the floor level at the front edge of the second row seat is 3 ft 8 in. below and 18 in. in front of the eye position. Repeat steps (1), (2), and (3) to the back of the house and draw in the floor slope. Where the slope exceeds 1 1/2 in. per foot, platforms are required under the seats, and steps in the aisles. A cross aisle which divides the orchestra into front and back sections entails the elevation of the first row of seats behind it to make up for horizontal width of the aisle.

The standing spectator's eye level behind the rear row of seats is assumed to be 5 ft 6 in. above the floor level of the last row. The sight line from this position to the top of the screen or highest probable curtain trim establishes the minimum height for ceiling under balcony. (See Fig. 21.)

Raising the stage will make it possible to reduce the floor slope but at the penalty of producing upward sight lines in the first two or three rows which are uncomfortable and unnatural for viewing stage setting and action. If the stage floor is above the elevation of the first row eye position, the upstage floor out of sight by perhaps as much as 6 in. from the first row is generally preferable to having an excessive floor slope, especially if more than one balcony is used.

When planning for motion pictures only, the lower sight line from the first row will come to the bottom of the projected picture, approximately 24 in. above the stage floor, or still higher if a reverse floor slope is planned.

In laying out the balcony, sight lines are laid out from rear to front because it is unsafe to change balcony slope. The focal point onstage is the point farthest downstage at which visibility is requisite, or, in the case of motion pictures only, the bottom of the screen. The maximum forward extensivity of the balcony is then determined when the location of the spectator's eye position has been moved forward to a point beyond which the floor and supporting structure would intersect the upper sight line of the spectator standing at the rear of the orchestra.

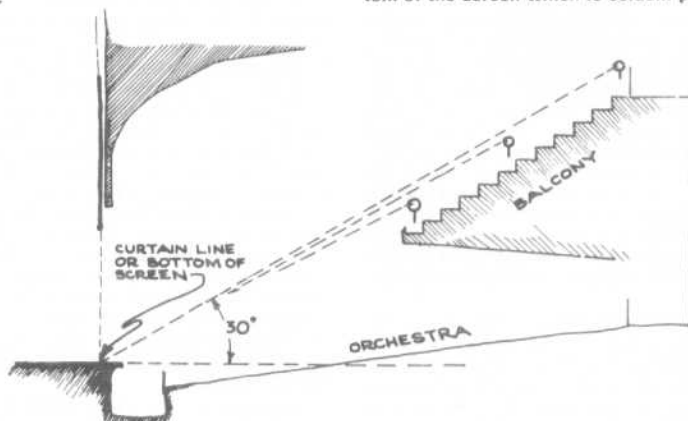

Fig. 19 Maximum tolerable downward sight line angle from balcony.

Fig. 20 (a) Maximum tolerable upward sight line angle for motion pictures. (b) Maximum angle determines location of closest seats. (c) Basic dimensions for plotting floor slope.

The pitch of balcony floors should not change since that would entail a change of riser height for aisle stairs and introduce attendant hazards. If vision from the rear row in the balcony is adequate, the rest of the balcony is satisfactory.

In theaters designed only to show motion pictures, the first row need not be located so that the patron can see the stage floor. It is satisfactory if he sees without obstruction the bottom of closest seats which is seldom placed less

than 2 ft above the stage floor. Raising the screen makes it possible to flatten the contour of the orchestra floor. The reversed floor slope developed by Ben Schlanger makes use of this relationship to get the maximum number of seats into the zone of least visual distortion, and to hold the height of motion picture theaters to a minimum. A result of the reversed floor slope is to place balcony seats in the zone of optimum seeing.

Fig. 21 The sight line of the standing patron limits the balcony overhang.

It is apparent that a theater designed for maximum efficiency for motion pictures (reverse floor slope) is almost completely useless for any other sort of production except large-screen television. The principle survives in the angle of the car stands in the drive-in motion picture theaters.

Floor Dish

The planning of the floor slope is not completed when pitch of orchestra and balcony has been laid out on the center line. It depends also on the curve of the rows of seats. The whole row must be at the same elevation if the seats are to be level. The floor therefore is not a sloped plane, but a dish surface in which horizontal contours follow the seat row curve. The floor section at the center line, rotated horizontally about the center of curvature of the rows of seats, will determine the orchestra floor shape. The balcony is planned the same way save that the floor is terraced to take the seats. (See Fig. 22.)

Comment

It has been established that conditions of seeing limit the depth of the house. Since capacity is a function of depth and width, increasing the width increases the capacity. However, since sight lines from the side seats limit the angular spread of the side walls, the width can be increased only by increasing the proscenium opening. The width of the proscenium opening is a function of the kind of production contemplated for the theater. The dimensions given in Table 1 are derived from the requirements of the types of produc-

TABLE 1 Proscenium Widths, in Feet, for Kinds of Theatrical Production

	Minimum	Usual	Reasonable maximum
Drama	26	30 to 35	40
Vaudeville, revue . . .	30	35	45
Musical comedy, operetta	30	40	50
Presentation, opera	40	60	80

Fig. 22 Developed floor slope for unobstructed vision.

tion noted when the performances are so staged as to assure maximum effectiveness.

Where budget permits building to have better than minimum visibility standards, wall angles may be narrowed, floor angles increased, and balcony omitted, and visibility from the worst seats thereby improved to a point considerably better than what is just salable. A very real problem, however, is to prevent precedent or personal prejudice from so influencing auditorium design as to cause the inclusion of large numbers of unsalable seats. One manager insisted, after floor slope and stage height had been determined and the auditorium floor laid, that the stage floor be lowered some 10 in. below the height called for in the plan, in the interests of, as he put it, "intimacy." From the middle of the orchestra in that theater it is hard to see below the level of the actor's navel. (See Fig. 23.)

Greek theaters were semicircular (horizontal sight-line angle 90° to center line). This was all right in Greece where there was no proscenium. It is obviously not all right where a proscenium is used. Yet, a misguided reverence for ancient practice still gives us some theaters with impossible sight lines.

Fig. 23 Zone of invisibility. Causes: stage too high, front seats too low.

Opera houses of the Renaissance had side boxes for the very good reason that the people in the boxes competed (often successfully) with the stage show for audience attention. This condition persists, but it is worth noting that the best example of such a theater in America has not made a nickel for a generation. Nevertheless, theaters with at least vestigial side boxes are still built.

It is perhaps unnecessary to add that theaters planned in conformity with the principles here set forth may adhere in spirit to almost any architectural style by the discreet planning of service and decorative elements which do not affect the basic shape of the theater. In theaters which are being rebuilt, it is often possible to retain the desirable features and still provide a good theater.

Open Stage and Extended Stage

The open stage form in which sight lines must be directed to the edge of the acting area necessitates steep balconies. The balcony of a theater which is convertible from proscenium to

open stage form must follow the requirements for open stage. Any theater in which performance extends beyond the proscenium onto either forestage, open stage, or extended stage requires very careful planning to provide good seeing from all balcony seats to all parts of the acting area.

Arena Stage

Few, if any, arena-form theaters have balconies, nor are they likely to have since the all-around seating of the arena form seems to satisfy seating capacity demands without balconies. Moreover, to satisfy the requirements of good seeing in arena, it is necessary to elevate successive rows of seats more than in proscenium form as a partial solution of the insoluble problem of actors covering other actors from some spectator's direction. (See Fig. 24.)

If seat rows are successively and sufficiently elevated, the audience may see over the heads

Fig. 24 The sight line problem inherent in the arena form: A hides B and C from first two rows.

of near actors to the heads, and partially the bodies, of actors farther away.

The stage is easily defined: it is that part of the theater where the performance takes place.

Its size, shape, arrangement, and equipment, therefore, must logically develop from the nature of the performance. Inasmuch as architectural acoustics and the electronic control of sound can provide for optimum audience perception of the auditory components, regardless of the form of the stage, development of the requirements for the stage may proceed from a consideration of the visual components and the routine of performance.

STAGE SPACE

For all production types, the visual components divide into two categories: performers and scenic investiture. These indicate the functional divisions of the stage: (1) the space in which the performers work, which, though actually three-dimensional, is usually referred to as the acting area, and (2) the space wherein the scenic investiture is arranged, which will be called hereafter the scenery space. A corollary of the presence of scenic investiture is the need for its operation and storage. This indicates a third functional division of the stage: working and storage space.

There is a functional relationship between acting area, scenery space, and working and storage space. The size, shape, and arrangement of the acting area must be determined before the other spaces can be logically developed. (See Figs. 25 and 26 and Table 2.)

Performance-Audience Relationship

The theater situation is fundamentally one of the relationship between the performers and the audience. The audience wants to hear and see the show without distraction and in comfort and safety, as stated, but its ultimate objective in attending the show is to receive the utmost sensory stimulation toward the maximum emotional and intellectual experience. Maximum appreciation and enjoyment of, and in a very real sense participation in, the theater experience by each individual member of the audience depend upon the maximum enjoyment of it by the entire audience. Group reaction to a single performance stimulus is something less than total unless that stimulus be perceived at the same time, in the same measure, and with the same significance by the entire group.

Cultural

THEATERS

Stage Space

TABLE 2 Spatial Requirements for Various Types of Theatrical Productions

	General characteristics	Acting area size	Shape
Pageant and symphonic drama	Dramatic episodes, processions, marches, dances, and crowd scenes. Masses of performers engaged in simple but expansive movements before very large audiences.	From 2,000 to 5,000 sq ft, depending on the scale of the pageant.	Rectangular with aspect ratio between 1 to 3 and 2 to 3.
Grand opera	Large numbers of performers on the acting area at one time; often more than one hundred in big scenes and finales. Movement is martial processions and group dances and the costumes are elaborate. Soloists perform downstage center, close to the footlights but within the bounds of the conventional proscenium, principals play twosome and group scenes in the area near the audience, and choruses and supernumeraries require space upstage. The ballet and the chorus of soldiers, pilgrims, peasants, or what not, sometimes fill the entire acting area. The performance is viewed objectively by the audience and does not benefit by intimate contact between performance and audience.	Minimum: 1,000 sq ft Usual: About 2,500 sq ft Reasonable maximum: 4,000 sq ft	Quadrilateral with an aspect ratio between 1 to 2 and 2 to 3. Sides converge toward the back of the stage, following the sight lines from the extreme lateral positions.
Vaudeville, revue	Vaudeville and revue emphasize the human scale. Although the vaudevillian keys his performance for the last row in the gallery, the form is characterized by intimate direct relationship between performer and audience: monologues straight to the front, confidential asides to the front row, and audience participation in illusions. Other acts (acrobatics, etc.) are played across the line of audience vision for maximum effect.	Minimum: 350 sq ft Usual: About 450 sq ft Reasonable maximum: 700 sq ft	Rhomboid with aspect ratio about 1 to 3. Sides converge toward back of stage following the sight lines from the extreme lateral seats.
Dance	Graceful and expressive movements of human figures in designed patterns, chiefly in two dimensions but with the third dimension introduced by leaps and carries. Occasional elevation of parts of the stage floor. Singles, duets, trios, quartets, groups. The movement demands maximal clear stage space.	Anything under 700 sq ft is constricting. Reasonable maximum: 1,200 sq ft	Rhomboid with aspect ratio about 3 to 4. May project into and be surrounded by audience (open stage or arena) since frontal aspect of performers has minimal and space-filling quality has maximal significance.
Musical: folk opera, operetta, musical comedy, musical drama	These forms embody on a smaller scale the production elements of grand opera, plus a certain freedom and a quest for novelty which encourage the development of new performance devices. Close audience contact of soloists and specialists is borrowed from vaudeville and revue. Big scenes involve many dancers, singers, and showgirls, often with space-filling costume and movement. Fifty people on stage at one time is not unusual.	Minimum: 600 sq ft Usual: About 1,200 sq ft Reasonable maximum: 1,800 sq ft	Proscenium: Rhomboid with aspect ratio between 1 to 2 and 2 to 3. Sides converge toward the back of the stage following the sight lines from the extreme lateral seats. Arena: Circle, square, or rectangle (3 by 4 aspect ratio) or ellipse (3 by 4 aspect ratio).

Arrangement	Proscenium	Orchestra	Comment
Long dimension of acting area perpendicular to general sight line. Audience entirely on one side, elevated to perceive two-dimensional movement. Large openings at ends and in side opposite audience for processions, group entrances, and exits. Some elevation of portion of acting area opposite audience, purely for compositional reasons.	Either no proscenium with performers entering the "pageant field" from beyond the lateral sight lines, or structural or natural barriers to delineate the side limits of the acting area and conceal backstage apparatus and activity. "Curtains" of sliding panels, lights or fountains for concealing the acting area; often the concealment is by blackout only.	Space for 100 musicians between audience and acting area. Conductor must see performance.	Primarily an outdoor form, it is often staged in makeshift or adapted theatres, utilizing athletic fields and stands or natural amphitheatres. A few permanent pageant theatres have been built.
Long dimension perpendicular to the general sight line. Audience elevated to perceive two-dimensional movement.	Width equal to the long dimension of the acting area.	Pit for 60 to 80 musicians. Conductor must have good view of action.	Movement in two dimensions in acting area is a significant visual component, predicated elevation of the seating area to make this movement visible.
Long axis of the acting area perpendicular to the optimum sight line. Audience grouped as close as possible to the optimum sight line. The forestage is an essential part of the acting area; steps, ramps, and runways into the house are useful.	Width equal to the long dimension of the acting area. Flexibility is to some advantage in revue but of little value in vaudeville.	Music and music cues closely integrated with both vaudeville and revue performances. Pit space for from 15 to 30 musicians. Conductor and percussionist must have good view of the action.	Most of the visual components of vaudeville and revue are such that they are perceived best in the conventional audience-performance relationship. The comic monologist who must confront his audience is defeated by the open stage and arena arrangements.
Nearly square acting area so that dance patterns may be arranged in depth and movement may be in many directions including along the diagonals. Many dance figures require circular movement. Many entrances desirable, especially from the sides of the acting area.	Proscenium not really necessary; though useful as concealment for lighting instruments and dancers awaiting entrances, other devices such as pylons, movable panels, and curtains may be substituted.	Music almost always accompanies dancers. For dance as part of opera or musical show, orchestra is in pit. For dance as specific performance, as in ballet, orchestra may be in remote location and music piped in. Maximum orchestra for dance: 60 musicians in pit for classical ballet. Minimum: one drummer.	Dance in its various manifestations is the performance form best suited to the open stage or arena since it possesses the least amount of facial-expression significance and the greatest amount of movement and pattern in two or three dimensions. Elevation of the audience to perceive best the patterns of dance is desirable.
Proscenium: Long axis of acting area perpendicular to the optimum sight line. Mechanized mobility of structural parts to produce changes in acting area arrangement are desirable. Forestages, sidestages, acting area elevators. Arena: Numerous wide entrances for actors and stage hands via the aisles or through tunnels under the seating banks. Ramps preferable to stairs or steps. Experimentation possible in rendering stage flexible by lifts, and in development of flying systems over the acting area.	Usually as wide as the acting area, but should be adaptable to changes in the arrangement of the acting area described in the preceding column. Arena: None	Music an integral auditory component, sometimes integral visually. Elevating orchestra pit to accommodate from 20 to 40 musicians. Arena: Orchestra pit beside the acting area parallel to long axis and opposite principal entrance. This unavoidably imparts a performer orientation toward the orchestra and favors the seats in that general direction.	The assumption by ballet of a greater share in the performance of musical comedy indicates the need for a high general sight line from the audience. A phenomenon of the last 20 summers has been the growth of the musical theatre arena under canvas by which huge audiences have been enabled to see revivals of standard and Broadway musicals at popular prices though with general reduction of scenic investiture to that which is possible in the arena form. The movement has been economically feasible and generally profitable.

TABLE 2 Spatial Requirements for Various Types of Theatrical Productions (Continued)

	General characteristics	Acting area size	Shape
Legitimate drama	Of all production types, legitimate drama places the greatest emphasis upon the scale of the human actor. The importance of the individual actor requires that stage space and scenery do not dwarf him. Dominance of plot, locale, and characterization requires verisimilitude in the size and relationship of scenic objects. Too small an acting area crowds actors and furniture, hampers stage action, and detracts from the dramatic effect which is the sole aim of the performance. Too large an acting area diminishes the actor in scale and renders his performance ineffective by weakening the effect of his gestures and movement.	Minimum: 240 sq ft (12 by 20 ft) Usual: About 525 sq ft (15 by 35 ft) Reasonable maximum: 1,000 sq ft (25 by 40 ft)	Proscenium: Quadrilateral with an aspect ratio about 1 to 2. Sides converge toward the back of the stage following the sight line from the extreme lateral seats. Open stage: Semicircle, quadrilateral, or polygon projecting from a proscenium or from an architectural facade. Arena: Circle, square, rectangle, polygon, or ellipse with about 3 by 4 aspect ratio. Entrances from diagonal corners and in middle of one or both long sides.

Total Uniform Effect

If the theater does not permit total uniform stimulus and reaction, the performance can never reach its peak of effectiveness. The best efforts of theater artists stand the best chance of appreciative reception by audiences if the audience-performance relationship fosters total uniform stimulus and reaction, hereinafter called *total uniform effect*.

The producer and the theater artists have requirements consistent with these: they want the physical facilities which will allow their show to stimulate the audience to the maximum of intellectual and emotional appreciation. The skilled theater artist applies knowledge of audience reaction to the preparation of every part of the performance. If, because of inadequacies of the theater building, the audience cannot perceive the performance as the artist has planned it, the artist fails through no fault of his own, and the audience is disappointed.

Not only is it the height of theatrical artistry for the showman to achieve this condition of total uniform effect, but it is good business. The spectator who does not see or does not hear or

does not comprehend a speech or action because of inadequate physical orientation toward the performance feels to some degree cheated of his admission fee and less inclined to return to the theater than does the spectator who perceives all the components of the performance fully and who feels that the performance is projected toward him and those close to him.

Expert showmen and artists use their production knowledge and skills to the fullest within the limits of the physical plants at their disposal. It is the duty of the theater planner to provide them with facilities which neither limit nor hinder their efforts.

The performance and the audience can be related to each other in a limited number of combinations with some degree of variation possible in each arrangement.

Performance-Audience Arrangements

Audience Looking in One Direction toward the Performance: Proscenium This has been the conventional arrangement of the twentieth-century

theater in the United States. It has the following attributes:

It affords the maximum confrontation of performers and audience and is best for lecturers, concert singers, recitation and dramatic presentation. It establishes a limited orientation of performers to audience. The audience

Fig. 27

being in one compact group within a narrow horizontal angle, the performers can relate their actions to the whole audience simultaneously. (See Fig. 27.)

It creates a limited, unified, fixed frame for the pictorial composition of the performance. Scenery can approach the quality of fine art in the refinement of its design elements.

It permits the director and designer to relate performers to scenery, secure in the knowledge that the whole audience will perceive the relationships in the same way.

It is the best arrangement for presenting to an audience a dramatic action of conflict or opposition of forces because the line of action of the opposition or conflict is across the line of vision of the audience and hence is maximally perceptible.

It is the form most conducive to the production of total uniform effect.

Being the established conventional form, it stands vulnerable to attack by avant-gardists who often seek change for the sake of change.

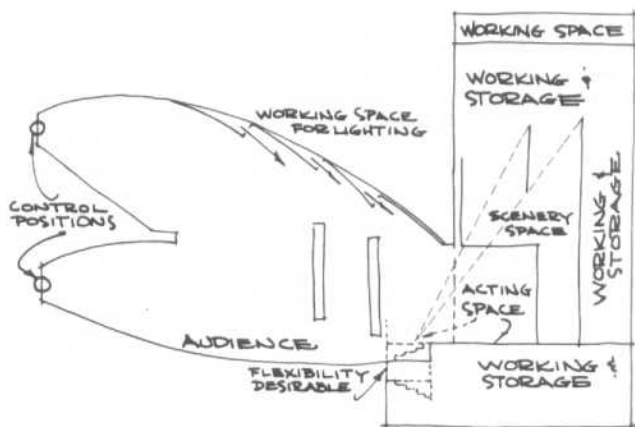

Fig. 26 Position of backstage spaces.

Arrangement	Proscenium	Orchestra	Comment
<p>The realistic style of dramatic production confines the performance to an acting area entirely inside the proscenium. The apron is not used. Most historic styles and much modern dramatic theory demand more freedom of audience-performance relationship than the realistic style and call for the projection of the performance toward, into, and around the audience. For this projecting aprons, forestages, sidestages, runways, steps and ramps into the aisles are all to some degree useful. To meet the demands of different styles and stylists, the acting area for drama must be capable of assuming many shapes. To confine it within the proscenium opening is adequate for the realistic style but inadequate for the others; to project it toward, into, or around the audience in any rigidly unalterable form is likewise adequate for one style but inadequate for others.</p>	<p>Width equal to long dimension of the acting area. Moving panels to vary width, openings in proscenium splay to form side-stages, movable pylons or columns by which opening may be subdivided are all desirable. Flexibility and mobility are increasingly desirable. The application of motive power under remote control to the movement of structural parts to produce different arrangements appears desirable but is costly. Manually alterable parts, particularly forestage proscenium panels and sections of the stage floor, if not unwieldy, are reasonable substitutes.</p>	<p>Orchestral music is sometimes an integral visual part of the performance, but most generally it is a purely auditory component. It is not generally necessary for the orchestra to be seen by the audience, but because cueing of music is so exacting, the conductor must see the action. It is reasonable to provide a pit for from 15 to 30 musicians, but the flexibility cited at the left must be provided, either by portable pit covers, steps, and platforms or by mechanized orchestra lifts. There is opportunity for originality of arrangement.</p>	<p>The various forms of theatre used by legitimate drama are discussed fully earlier in this chapter.</p>

It is limited in seating capacity because the principal direction of expansion is away from the performance; the limit of good seeing becomes the limit of expansion. Expansion laterally tends to destroy total uniform effect by making occupants of the side seats view the performance from widely divergent angles and thus see the actors, action and scenery in non-significant relationship.

Theatrical production refuses to be contained within a strictly limited space behind a rectangular opening. The existing proscenium form has been called the picture frame stage, and the peep show stage, and even during its incidence and rise to prevalence there were objections to its restrictive character. The theory of theater admits, and numerous modern plays contain, instances where the contact between performance and audience must be more intimate than the formal frame permits. History of theater shows 24 centuries in which the picture frame was either nonexistent or modified by the use of acting areas in front of it, against the last century and a quarter during which the proscenium developed in prominence. Modern theatrical practice contains frequent instances of the performance's attempting to come through the frame, into, about, and around the audience.

Audience Partially Surrounding the Performance: Open Stage In several variations this arrangement has gained in popularity during the midcentury. Essentially an old arrangement descended from Greek, Roman, Renaissance, and Elizabethan theaters, it has been readopted for several reasons:

It places the performers in the same space envelope as the audience. This is said to produce a unity of experience between performers and audience, though the authors believe that the essential dichotomy of function between performers and audience persists regardless of spatial relationship and that attempts to resolve this dichotomy are futile, fallacious, and irrelevant. (See Fig. 28.)

It places more spectators closer to the performance than does the proscenium arrangement and in this way contributes to good

Fig. 28

seeing, but it places a burden of diffused orientation upon directors and performers and makes impossible the achievement of total uniform effect.

It contains inherent difficulties in the entrance and exit of actors which are usually solved by providing entrances beneath the seating area.

Difficulties pertaining to the scenic investiture which are common to both this arrangement and the arena arrangement will be considered together.

Audience Surrounding Performance: Arena or Central Staging Various called *bandbox*, *arena*, *theater-in-the-round*, *circle theater* and deriving certainly from circus, ancient amphitheatre (*double theater*), and primitive ritual sites, the arrangement of the acting area in the center of a surrounding ring of audience has gained in popularity in the twentieth century for a number of reasons:

E expediency. At a time when formal theaters have been decreasingly available and increasingly expensive to build, while simultaneously the number of play production groups has been increasing rapidly, the arena arrangement, achievable in any large room, makes a rudimentary theater possible.

Economy. As well as seating maximum audience in the minimum enclosure, this arrange-

ment seats the largest audience within the shortest distance from the acting area. It is therefore attractive to the showman and also to the spectator who attaches value to proximity to the stage. (See Figs. 29 and 31.)

The claims of intimacy which are voiced for the open stage arrangement are repeated for the central stage and the same demurrers apply with the additional statement of positions *pro* and *contra* the feature of seeing the audience across the acting area. The argument *pro* is that seeing other members of the audience enjoying the show stimulates one's own enjoyment. The argument *contra* claims that the opposite audience seen beyond the actors is no part of the performance and is therefore a negative factor to the degree that it is distracting. It is surely a negative factor in that it is not a part of the design and plan of the performance; it is not scenic investiture.

Economy is also affected by the effective limitation of scenery: There can be no scenery or properties that the audience cannot see over, under, or through. This restricts scenic investiture to paint or other coverings on the stage floor, very low platforms, devices suspended above the acting area, outline representations of such objects as must be set on the

Fig. 29

THEATERS

Stage Space

stage for use by the actors (doors, windows, and similar architectural details), and low pieces of furniture.

Disadvantages. Because the audience is seated all around the acting area, it is unavoidable that viewpoints will be maximally different and it becomes impossible for director and actors to compose the performance so as to produce a total uniform effect. Furthermore because the conditions of *covering* (one actor blocking audience vision of another actor) are also maximized, it is necessary to prevent covering by increasing the pitch of the seating area.

An unavoidable disadvantage of this form lies in the anterior-posterior aspect of every actor and the fact that the most dramatically expressive side is oriented in only one direction. The summary comment on this aspect was made by the late David Itkin: "I have seen one-half of the show; now I will buy a ticket on the other side of the house and see the other half of the show." Unfortunately, because the performance must (at times) be oriented

toward the sides where he has not yet sat with his two tickets, he would have had to buy two more tickets, four in all.

Performance Extending around Audience: Extended Stage Various called *side stages*, *multi-proscenium*, *theater-all-around*, and even *theatrama*, this arrangement has gained some acceptance in the midcentury decades. (See Fig. 30.)

This form begins as an extension of the conventional acting area to left and right, usually as *paradoi* entrances on the audience side of the proscenium, or as doors in the side wall spalls which may be used when desired as frontal entrances onto the stage. Its fullest development is in the four-stage form which requires that the audience sit in swivel chairs.

Its uses in production are various:

1. Small scenes played on side stages while scenery is being changed on the main stage.
2. Processions entering from the side stages and moving into the main stage.
3. Expansion of acting area for simultaneous showing of several settings or locales.

4. Elimination of changes of scenery by having all scenery set up on the various stages and moving the action and even rotating the audience. (This form relates directly to the television studio method of having several settings set up and moving actors and cameras from one set to another.)

Fig. 30

Fig. 31 Arena stage, Washington, D.C. Architects: Harry Weese & Associates. Consultants: Bolt, Beranek & Newman. The arena stage (capacity 752) is an octagonal-shaped theater-in-the-round with a rectangular performing area. One of the four tiers of seats is removable to permit a three-quarter arena form. The stage floor is trapped to provide additional staging flexibility and to provide an orchestra pit when the three-quarter arrangement is used for musicals. The height of the catwalk-lighting grid from the stage floor is also adjustable. The building was designed for a resident, professional, repertory company.

The community theater usually contains 500 to 1,000 seats and serves amateurs, semiprofessionals, and visiting professional groups. Most of the scenery and costumes are designed and made at the theater and require a special type of workshop. Because of its varied use, and the rather indeterminate responsibility of its management, its planning should be as simple and as foolproof as possible. This study will not include experimental theaters, since these present special problems.

A properly selected site offers (1) Accessibility by normal means of transportation. (A central location is essential for walking only. Automobiles should not have to traverse congested traffic zones when this can be avoided.) (2) Sufficient separation from bus and streetcar lines, principal highways, and other sources of noise. (3) Parking space. (4) Convenience to complementary community activities, educational or recreational, in order to reduce interbuilding traffic and minimize supervision and maintenance.

ARRANGEMENT

"Front" or public areas, and "backstage" or work groups, constitute the two major elements. Spectators should find everything necessary for their needs accessible from the foyer once they have presented tickets. Included are toilets, coatrooms, drinking fountains, lounges, and smoking areas. The lobby should provide waiting space and circulation to areas other than the theater, which may be contained in the building. The manager's office is convenient if adjacent to the box office and accessible from the lobby. In the work group, control of the stage entrance will avoid interference from unauthorized persons and facilities.

Time-Saver Standards, 1st ed., McGraw-Hill, Inc., New York, N.Y., 1946.

tate accounting of players, properties, and scenery. Rehearsal rooms are part of the work area and should be near other work elements. Movement of heavy furniture and other properties demands close relation between work spaces and stage proper. Dressing rooms may be more remote but within supervisory distance. (See Fig. 1.)

GENERAL REQUIREMENTS

Requirements for community theaters, although derived from the same sources and from the same historical background as those of the commercial, or "professional," theater, exhibit fundamental differences. Emphasis upon creative effort leads to demands for a different type of accommodation than does the necessity for financial profit. Two general types of creative community activity, directly related to the theater, require special provisions.

Audience Activity This is great before and after a performance and between acts, due to the social nature of the occasion. Spaces for lounging, talking, smoking, are all necessary. Easy access to such spaces is of prime importance. At times, audience and actors may intermingle; for this a combination of lounge and rehearsal room is needed. Since refreshments may be served, a small kitchen or serving pantry is essential.

Production Activities These consist of preparation for and presentation of the performance. In a community theater, scenery, costumes, and properties are mostly prepared within the theater plant. Separate workshops are ordinarily provided, one for costumes, and one for scenery and properties. Used materials are salvaged insofar as possible, stored within the plant, and reused. Ample storage space is needed.

Presentation problems may be solved differently in the community theater than in its commercial prototype. Both types demand ample stage space; but, whereas in the "professional" theater, urban real-estate values have forced a vertical development with lofty stage houses for lifting scenery vertically ("flying"), tiered dressing rooms, and often inadequate wing space, the community theater, built on less expensive land, may be expanded horizontally. Scenery can be shifted horizontally, perhaps on wagon stages. Proscenium size and shape may be variable. Such flexibility and multiplicity of uses are not only financially desirable, but some theater authorities call them essential for the theater's progress. Types of stages which are considered impractical in the average commercial theater, become available.

Limitations Because the theater has such highly specialized requirements, this study is limited in scope to those items within the creative center which are strictly community theater needs. Emphasis in the community theater being on amateur participation in all phases of the theater, there is to be expected less efficiency of personnel, and a necessity for greater

flexibility of facilities, than in commercial theaters.

Capacity of the auditorium for the type of theater here discussed averages approximately 800 persons, often less. If, for financial reasons, provisions for road shows must be included, minimum seating capacity has to be increased to 1,200, preferably 1,500 persons. This increase brings many disadvantages, among which are lack of intimacy and lack of flexibility in auditorium shape and stage type.

Public Circulation A prime requisite for public areas in the community theater is ease of movement. Access between the various parts needs to be as free as possible, to permit their full use by the audience before the show, between acts, and after the final curtain. Code requirements as to doors and exits are minima for safety; the community theater needs even greater circulation facilities. Depending upon site, nature of surrounding developments, disposition of plan elements, and requirements for acoustics, lighting, etc., the number of openings to vestibule, lobby, auditorium, and lounge may be increased far beyond the minimum.

Access to Auditorium If possible the principal entrances from the lobby to the auditorium should be arranged without doors. In order to achieve this it is necessary to make a careful acoustical analysis; in all probability sound-deadening material will be required on the walls of approaching corridors or lobbies, to prevent parallelism.

Types of Space It is always desirable to have both vestibule and lobby. In most cases, it would be well to provide a separate lounge which on occasion may be used for social meetings, lectures, discussion groups, etc. The lounge may also serve as rehearsal space.

Vestibule The lighting in the vestibule adjoining the street may be quite brilliant. Telephone booths should be provided, accessible from the vestibule. In general the addition of other features, such as small bookstores, etc., which will attract the public to the theater as a part of their daily lives, is desirable.

Ticket Office This should, if possible, both command the entrance to the inner lobby and at the same time permit the lines to form without obstructing it. There are preferably two ticket windows, one for reserved seats and one for current seats. Necessary also is sufficient free wall space for a small ticket rack which can be made locally.

Lobby While the theater in the large city has no particular need for oversize lobbies, in the community theater the performance must be considered as a social occasion as well as dramatic entertainment. Therefore, the lobby should be arranged to show off groups of people and their clothes to advantage.

A combination of exhibition space and lobby is easy to achieve, and is generally desirable in the community theater. It is hoped that the community will take an interest in the produc-

COMMUNITY THEATERS

Community Theaters

Typical space requirements			Typical Space Requirements		
Spaces	Areas* (sq ft)	Remarks	Spaces	Areas* (sq ft)	Remarks
Vestibule and gallery	1,200	Less area would hamper use of space as gallery and meeting place. Area may be increased in proportion as auditorium capacity exceeds 800. Good lighting is necessary.	Stage	3,500	Ample; 2,800 sq ft minimum; 3,500 usual avg. except for encircling stage. Air conditioning in conjunction with auditorium desirable; no outside light; top of stage house louvered (consult codes); if conventional stage, minimum height, floor to grid, is 70 ft.
Checkroom	240	Minimum unless checkroom does not serve auditorium or unless patrons do not check overcoats.	Stage workshop	1,500	Sometimes reduced to 1,200 sq ft. Outside light, if clear glass, preferably from north; if obscure, orientation unimportant.
Lobby	1,000	See Vestibule; mechanical ventilation needed here.	Scene storage	1,000	Minimum; larger if possible.
Ticket office	50	Minimum; for larger houses additional administration office (50-80 sq ft) is required. Ticket windows (2) and wall space (approx. 4 by 8 ft) are necessary.	Costume workshop	420	May reduce to 300 sq ft; north light desirable.
Lounge-rehearsal room	750	Minimum size, equal to acting area of stage; mech. vent. needed.	Costume storage	210	Minimum; no outside light; preferably ventilated; must be dry.
Administrative	350	Minimum; area varies. Outside light and air needed.	Costume dyeing	80	Minimum; no outside light required; unless outside air provided, must be mechanically ventilated.
Men's toilets	250	Consult codes; areas ample for 800 capacity; either mech. vent. or outside light and air needed.	Six dressing rooms†	680	Each room requires access to two lavatories; size not changed with size of building; stars' dressing rooms each need private toilet and shower; all preferably air-conditioned.
Women's toilets	250		Makeup room†	130	Minimum; used also for dressing, requires two lavatories; preferably air-conditioned.
Auditorium	5,800		Two chorus rooms†	440	Reasonable minimum; three lavatories needed in each; preferably air-conditioned.
Radio studio	300	Can be reduced to 200 sq ft; no outside light; mech. vent. needed.	Two bathrooms	300	Reasonable minimum.
Control room	70	Minimum; mech. vent. needed.	Stage manager	150	Minimum.
Director's room	20	Minimum, but adequate.	Discussion room	750	Can be used for rehearsal; area determined by acting area.
Quiet room	30	Acts as sound insulation between circulation and radio unit.			
Projection room	200	Ample, includes toilet and lavatory; consult code requirements.			
Spotlight booth	400	Area may be divided into three booths: one on center with stage, one at each side of auditorium.			

* Based on auditorium capacity of 800.

† Dressing, chorus, make-up rooms require mirrors, preferably 3-sided type, movable; and overhead lighting, mirror-lighting equipment.

tion of a play as well as in its presentation, and, therefore, exhibition space is desirable to show the various developments: costume designs, sketches for stage settings, etc., even though the space is not used as an actual art gallery.

Checkroom This should be either adequate or omitted entirely. If included it should open from the main lobby and provision should be made to have a sufficient number of attendants and a sufficiently large opening to the lobby so that standing in long lines after the performance is not necessary. In community theaters the expense of the proper number of attendants may become a problem. The checkroom serves not only the theater, but also other facilities in the building, and therefore should have an entrance to the main vestibule.

Auxiliary Spaces These include areas not always essential to the theater, but usually desirable. Projection rooms are fairly well standardized. If provisions for radio broadcasting are desired, for either instruction and study of new dramatic techniques, or actual broadcasting, the minima outlined in the table above may be provided. Discussion or viewing rooms are

similar to radio studios, and, like them, usually need loudspeakers. Here an instructor and class, or the theater director and assistants, may discuss a production freely while it is in progress.

AUDITORIUM AND STAGE

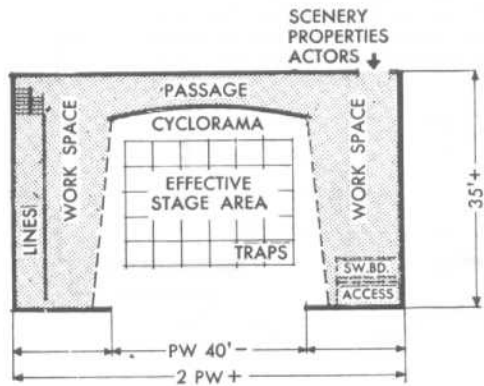

Maximum Seating Distance Even in theaters of 1,200 to 1,500 capacity, the last seat is preferably not over 75 to 100 ft from the stage, and much less in smaller houses. When balconies are used, the front of the balcony is preferably within 50 ft of the stage.

Sight Lines The apron of a forestage may be excluded from view to prevent sight lines angled sharply downward from rear seats. In auditoria of 800 or less capacity, when balconies are not used, a complete view of the forestage should be possible. Side proscenias of encircling stages do not require perfect sight lines; balconies may help improve them. Sight lines for the side seats in the auditorium should permit a minimum of two-thirds of the main acting space to

be seen through the conventional proscenium; conversely, care should be taken that areas beyond the acting space are masked.

Seating Facilities Seat spacing preferably always exceeds the minimum of the New York Code of 32 in., back-to-back; and, if possible, seats are not less than 20 in. on centers. Use of "Continental" seating, in which each seat row becomes an aisle, should be limited to small auditoria, where it does not force the rear row to be located too far from the stage. Aisle widths and number of aisles are generally determined by building codes.

Auditorium Capacity and Type Need to vary the capacity of an 800-seat auditorium is not urgent. However, when necessary, this may be accomplished with curtains, placed in such a way, perhaps under the lip of a balcony or at a natural break in the auditorium, that they do not appear to change the essential proportions of the auditorium. Empty seats visible to actors are a detriment to good performances. Experts should be consulted as to the acoustical effect on the auditorium. A solid partition will very probably cause havoc in the acoustics.

Rigging Diagram

STAGE DIAGRAMS

Advantages or disadvantages of stadium houses versus balconies are subject to much discussion. The best opinion seems to agree that a stadium house for a capacity of over 800 or 1,000 will have a rear row of seats too far from the stage for "comedies of errors," although satisfactory for spectacle pieces.

Auditorium Lighting The object of lighting in the auditorium is to concentrate attention upon the stage, even before the curtain goes up. In most cases, lights with reflectors, in coves hidden

from view, will prove most satisfactory. Fluorescent lighting, though efficient, is difficult to use because it cannot be dimmed. The color of the light should be neutral though warm. Chandeliers are usually considered objectionable.

Stage Area Space is the most vital consideration. It is necessary that the stage be so arranged that up to five sets can be set up and stacked in succession, without being seen during the performance; and that this be done

without acrobatics on the part of amateur stage hands. Furthermore, open-air (plein-air) scenes require the appearance of great height. Again, a high stage loft and an expanse of unimpeded wall space are desirable for storing current sets. This means confining openings to one wall if possible, or, at the most, two. It is also necessary that the stage provide a "crossover," i.e., a passage for actors across the stage, either behind the stage through a corridor, possibly through the stage shop, or behind the cyclorama.

SEATING AND AISLE ARRANGEMENTS: Heavily shaded areas represent stage and seating area losses from comparative visual position in various systems.

COMMUNITY THEATERS

Fig. 2 Two of the many types of cycloramas; one on the right is difficult to adjust.

Acting Facilities The acting area extends slightly more than the width of the proscenium, and is, at the least, 20 ft deep. It should be trapped throughout its extent, with unimpeded space below.

All types of stages are preferably provided with an ample forestage. Even though this is not carried to an extreme, it is desirable for performances which are to be seen in the "round" rather than through a picture frame, and for soloists or lecturers. It can include provisions for removable seats, thus varying the auditorium's capacity.

The stage manager requires at least a desk, with direct access to stage, and to dressing rooms. The prompter needs a small space from which he can hear and follow action without being seen.

Scenic Provisions Cycloramas, or background surfaces, are illustrated by diagram and are

susceptible to great variation, both as to material, number of units, and shape. In planning for the type of cyclorama to be used, provision must be made for moving scenery horizontally. Permanent solid cycloramas, made of plaster, are particularly desirable for use only as a back wall of an encircling stage. Curves must be acute, and as a rule it will be found desirable to tilt the cyclorama back slightly to reduce objectionable sound reflection. (See Fig. 2.)

The *gridiron* consists of a number of structural steel shapes suspended from 70 to 90 ft above the stage floor. Its exact location and composition are best determined by a stage equipment specialist. The *pinrail* is located along one wall of the stage, and serves as a means of securing grid lines. It is commonly 14 to 15 ft above the stage floor.

Two doors, each at least 8 by 12 ft, are usually required for loading scenery. One should open to the scene shop, the other to a street or

alley. The latter door may be omitted when no provisions are made for road shows.

Revolving or elevator stages may also be desirable, but are often too costly.

Nonconventional Stages If great flexibility is required in the stage, as would seem desirable for the community theater, a greater amount of stage area and cubage may be added to the wings. With certain exceptions, it is obvious that a given amount of cubage up in the air does not have the multiplicity of use that it will have at stage level. The result may be a long, circular, low stage surrounding the better part of the audience, closed off from the auditorium by a series of panels which may be shifted at will. Gridiron is usually eliminated unless funds are available for both grid and "encircling" stage.

With this "encircling" type of stage, additional storage space should be provided adjacent to the shop; and scenes may be shifted on

Combined Green Room and dressing room for women's chorus (20 people). The Green Room is an actor's recreation and discussion space, to which a few visitors may be admitted. Lights and mirrors are similar to those in other dressing rooms.

Typical dressing room for four people. Overhead lights are necessary for adjusting wigs and costumes, and for final inspection of make-up. Lights at mirrors are preferably designed to illuminate the actors' faces evenly, rather than to light the mirrors.

Typical "Stars" dressing room for two people. Triple mirrors are desirable but not essential. Adjoining toilet should contain a shower and water closet.

At left, plan of typical costume shop. Good light, preferably natural, is essential for sewing machines. In many respects the costume shop is similar to the sewing department of a modern high school.

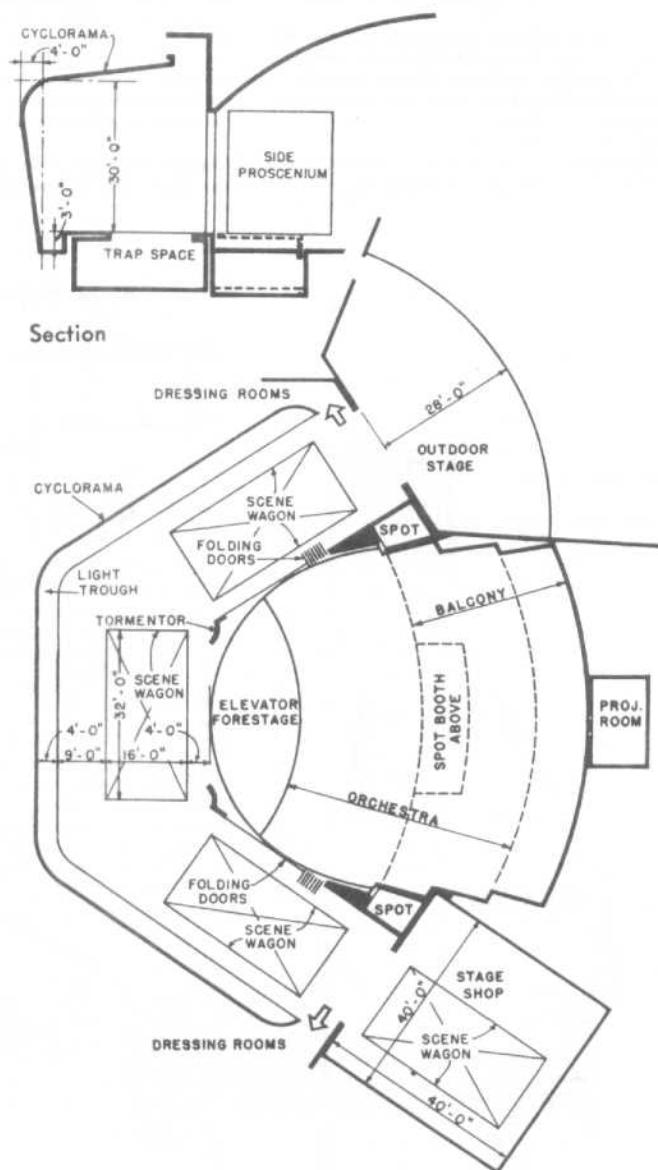

Section

Plan, conventional type of stage

Fig. 3 Stages.

Heavy dotted line in section of encircling stage indicates variable position of forestage. Cyclorama shown in conventional stage must be flown when scenery is brought in from shop. Trapped space on conventional plan, and center position of scene wagon on encircling stage, indicate acting areas. Scene wagons travel on tracks so wagons will clear cyclorama and tormentors. Since one purpose of the encircling stage is to facilitate other productions than the usual "picture-framed" type, emphasis on proscenium as a frame should be reduced to a minimum.

Plan, encircling stage (wagon-type)

In the stage shop are made scenery and properties. Facilities for woodworking, metalworking, and painting, and storage space for lumber, nails, tools, canvas, and painting materials, are all needed.

COMMUNITY THEATERS

wagons. When the encircling stage is used with all panels open, wagons are dispensed with and scenery is formalized. If structurally possible, the entire proscenium should be unimpeded by fixed columns. However, two columns placed at either side of an imaginary proscenium may be very useful for concealing vertical banks of lights. These light housings (in this case the columns) are called "tormentors," and are preferably movable. (See Fig. 3.)

Diagram of the encircling stage shows three spaces for two wagons (excluding the shop). If there is unlimited space, more wagons may be made available; but the ensuing complications are considerable and the gains small. The encircling stage becomes less practical as the size of the auditorium increases. Even with auditoria for 800, good sight lines are difficult to obtain unless stage area is substantially increased. It should be noticed, however, that productions which need side stages do not require perfect sight lines.

One may conclude that encircling stages are both economically and functionally desirable for the smallest auditoria, while for those of 800 seats and up, their cost may become prohibitive.

Outdoor Stage Size of outdoor auditoria varies considerably. The stage, of necessity, is some-

what formalized. If possible it should have immediate access to the inside stage, preferably through the wall, unless this arrangement is prevented by a built-in cyclorama.

Stage Shop Adequate area is a prime consideration. Equally important is the height to be allowed for the paint frame. When the conventional type of stage, with gridiron, is used, the height for a paint frame is at least 30 ft. Even with the comparatively low "encircling" stage, a 30-ft paint frame is necessary, since the effective height of scenery remains the same. It is possible to rig the paint frame on the rear wall of the auditorium, or on a stage wall. However, when this is done, no scenery can be painted on the frame during productions or during rehearsals. The shop is the center of most of the dramatic activities and includes subdivisions for carpentry, electrical, metal, and painting work. It should be provided with good outside light, preferably diffused. It should immediately adjoin the stage storage space, the desirable clear ceiling height of which is 15 ft. Less height can be used in storage spaces, but this necessitates laying flats on their sides, which is considered unsatisfactory.

Costume Shop This, too, is a vital element in the community theater, because, of necessity,

most of the costumes are made on the premises. The costume-storage space should adjoin the costume shop.

WORKSHOPS, DRESSING ROOMS, STORAGE

Dressing Rooms Requirements for individual dressing rooms vary, depending upon the likelihood of producing professional shows and the funds available. Most satisfactory would be provisions for 18 to 20 actors in a number of dressing rooms, each providing for 3 to 4 actors, and two chorus rooms, one for men and one for women, each providing for about 20 actors. One chorus room may be used as a Green Room or lounge for actors.

Rehearsal Rooms The number of rehearsal rooms is determined entirely by how much use is made of the building and how often the stage is available for rehearsal. Rehearsal rooms should be in the same proportion and somewhat larger than the acting area of the stage; and, acoustically, should reproduce stage conditions as closely as possible. The public lounge, adjacent to the auditorium lobby, may also serve for rehearsals.

Arts center. The proscenium stage at Sarah Lawrence College, Bronxville, N.Y. Architect: Marcel Breuer. Consultants: Stanley C. McCandless, E. C. Cole, Sidney K. Wolfe. This multipurpose auditorium (capacity 500) is steeply raked and the stage floor is low to allow better audience perspective, especially for dance performances. Alternate rows of seats are removable to permit installation of tables or desks. The lighting gallery is close to the stage so that the control board operator's sight lines are similar to those of the spectators. The backstage wall opens onto tennis courts so the stage may be used for outdoor performances, commencement exercises, and special events.

By SAMUEL SELDEN

NOTE: No fixed specifications have yet been drawn which are applicable to outdoor theaters everywhere. The following suggestions should be regarded as tentative, to be modified to suit particular local needs and available facilities.

THE SIZE OF THE THEATER

An outdoor theater can be planned to seat as many as 3,000 spectators without the use of amplification for the actors' voices. What is recommended, however, as an upper limit for the seating, is about 2,500. The suggestions in this outline are scaled for a structure of between 1,500-2,000 seats, which is nearer the ideal.

OUTSIDE THE THEATER

1. *Parking Lot (or Lots) should be—*
Large enough to handle one car for every three spectators.
Designed to permit convenient and speedy exit following the performance, with good access from traffic routes.
Surfaced with gravel or asphalt and provided with good drainage under all conditions.
Well lighted for ease and security in parking and walking.
So arranged as to permit the quick departure of any car in case of an emergency during the performance.
Convenient to the box office and the entrance to the theater.
Located where the noises and lights of late-arriving cars will not disturb the performance.
Well marked with signs.
2. *A Business Office*
If the theater is on or very near a main traffic route, the office of the manager may be placed at the theater.
Usual practice, however, is to have this office in the center of the nearest town where it is readily accessible to patrons stopping in hotels and motels.
In any case, the business office should have an information center and display space in addition to work space for the manager and promotion director and their assistants.
It should include a place for the display of folders, a desk for handling rooming accommodations, and the like.
3. *A Box Office*
Convenient to both the parking lot and the entrance to the theater.
With shelter for patrons buying tickets in bad weather.

Provided with windows for advanced sales, reserve seats, and general-admission (if any), clearly marked with prices.

With telephone connections to the business office (if not in the same building) and to the stage.

Near toilet facilities and a water fountain.

4. Other Facilities (Desirable Though Not Completely Necessary)

- A first aid station.
- A nursery for patron's children.
- A pay telephone.
- A concession stand or house.

5. The Entrance to the Theater

Well marked, simple, and attractive.
Near enough to the parking lot to keep older people from tiring themselves while getting to the theater.

Far enough away from the lot to let patrons lose the sound of traffic and fall under the quiet spell of the general setting before stepping into the theater.
Sometimes provision can be made for bringing very old or crippled patrons by car along a separate path right to the theater entrance.

6. A Separate Entrance and Parking for Cast and Crew

THE AUDITORIUM

Of primary importance are good hearing and good sightlines to every part of the performance areas. This means that an effective compromise must be made between width and depth. A very wide auditorium may have good acoustics but poor sight lines, while a very narrow auditorium will tend toward the reverse.

Effective acoustical planning depends on the correct placement of reflective surfaces for all sounds involved in the performance. Care must be taken, for instance, not to place opposing walls backing the side stages exactly parallel to each other (as they may cause a disturbing reverberation in the lower part of the amphitheater). Remember that the sound waves tend to bounce off mirror surfaces at the same angles that light does.

One of the first aids to good sightlines is an effective slope. Seats may be set on a rising parabolic curve, or on two different inclines, a fairly mild slope for the lower half of auditorium (the half near the main stage) and a steeper slope for the upper (rear) half. The slope recommended for the lower portion is 12° (that is, a rise of about 1 minute in 7), and for the upper 24° (about 1 minute in 3½) or steeper.

There should be at least five aisles, two down the center, two down the outside, and one cross aisle at the break between the two slopes. If the central seating area in the back section of the auditorium is very wide, it can be broken by an additional longitudinal aisle extending from the top down to the cross aisle.

All stepped sections should be illuminated by small hooded aisle lights.

The seating may be provided by sturdy wooden benches with plank backs, by benches surmounted by clamped-on plastic sport seats, or by individual metal seats with or without arms. If single seats are used, they may be so mounted or racked together that patrons will not shift them around.

The most satisfactory seats seem to be either sturdy metal and canvas folding chairs or chairs with tough, preformed plastic seats. These can be lifted for cleaning, tilted to avoid water puddles during a rain, and can be stored indoors when not in use at the close of the season. All seats should be clearly numbered. The width of each seat should not be less than 18 in. and need not be more than 23 in. A comfortable width is about 21 in. The distance between rows of seats should be 3 ft. Other details about the auditorium which need to be kept in mind are:

1. Toilet facilities, placed and housed where they are convenient to both sides of the auditorium but are not noisy, and of sufficient number to accommodate the peak requirements which occur just before performance and during an intermission.
2. Rain shelters on both sides of the seating area or at the back, for use in case of sudden showers.
3. Concession booths on each side (walled in to reduce the noise of refrigerators and the handling of bottles).
4. Good paving (not loose gravel which is very noisy) and good drainage everywhere.
5. Sufficient auditorium lighting to let patrons read their programs easily, and high enough to be out of their eyes.
6. Signs placed where they will indicate clearly to the patrons where the various sections of seats are, as well as the toilets and the refreshment centers.
7. A public address system for announcements to the audience on rainy nights.

THE STAGES

The usual arrangement of acting areas in an outdoor theater is a large main stage and two smaller side stages in front of the proscenium wall and to the right and left of the main stage. This plan allows for flexible and continuous action since, by taking a scene off to one of the side stages, it permits the technical crew to change a setting on the main stage. Thus the play does not have to be broken at any point, except for the intermission.

These features are recommended for the main (central) stage:

1. A level 3 ft above the base of the lowest row of seats in the auditorium.
2. A proscenium opening of about 70 ft.
3. A depth of about 40 ft from the line of the proscenium walls. (The apron in front of this line should be as narrow as possible.)
4. Plenty of wing space—at least 50 ft—at each side of the acting areas.
5. A height for the proscenium wall on each side of the opening of 16 to 18 ft and of a

AMPHITHEATERS

length sufficient to mask from the audience all activity back stage.

6. An appearance for the proscenium wall which is simple, fairly neutral, and thoroughly in keeping with both the natural setting of the theater and the style of the play being performed (log, board, stone, or brick).

7. Level ground, well drained and preferably surfaced with either cement or asphalt (where scene changing does not require a smooth clear floor, the dancers can be helped by giving them several inches of sand as a dance cover).

8. Some amphitheatres have been built with a second, slightly higher, level with one or two longitudinal steps leading up to it, about 20 ft upstage, in an effort to increase the variety of acting spaces available. Careful consideration should be given to its effect on scene shifting, dancing, or other theater uses before this is incorporated as part of the permanent design.

9. In some cases it will be necessary to include anchoring devices for jacks, flanges, and stage braces supporting heavy movable scenery set directly and permanently into the hard surface of the stage floor.

10. Electrical outlets for stage lighting and for the convenient attachment of cable to special effects such as campfires.

11. Circuits for an intercommunication system between departments.

12. Unless a steep embankment or a clump of tall trees can serve as an acoustical background, a high wooden or masonry wall should be erected behind the stage to provide a sounding board at the rear of the acting areas. There should be masking wings for side entrances on the main stage and for mounting of lighting equipment and for convenient scene shifting space. A back wall for a 70-ft proscenium opening would be about 110 ft.

These features are suggested for each of the two side stages (right and left of the proscenium opening):

1. A level 2 ft above that of the main stage (5 ft above the base of the lowest row of seats), with easy access from both backstage and the main stage.

2. The area covering a quarter of a circle with a radial center on the proscenium wall of the main stage, starting about 30 ft back from the opening (giving a cut-of-pie-shaped acting space on the side stage of about 30 by 30 ft with the curve toward the audience).

3. No proscenium frame of any kind is needed for this side stage (the proscenium wall of the main stage forms the rear wall for these side stages).

4. Three steps or a ramp at the front corner to connect the side stage with the apron of the main stage.

5. Level ground, drained and surfaced like the main stage.

6. A door or concealed passageway connecting this stage to the wing of the main stage for the use of actors.

7. Considerable working space, right or left, beyond this acting area for the manipulation, and possibly the storage, of scenery and properties to be used on this stage. (If these are to be stored backstage in a wing of the main stage and brought out front when needed, an adequately concealed passage should be provided for them.)

Careful thought must be given to the far background of the three stages. The view of the stage and beyond it to the trees or distant mountains should be attractive and mood-

creating from the moment the spectator first comes into the theater area.

THE BACKSTAGE AREA

In the wings:

1. There should be plenty of free space for the assembling of actors, the organizing of groups, and the massing of crowd voices for offstage effects.

2. Property tables should be placed in locations convenient to both sides of the main stage and the entrances to the side stages.

3. There should be adequate spaces for the storing and sheltering of the portable scenery units and properties.

4. There should be proper drainage in every part.

5. All the permanent wiring should be run under ground where it cannot trip the actors or interfere with the movement of scenery and properties.

6. Some controlled illumination should be provided for backstage operations, well shielded so no direct or reflected lighting will be seen by the spectators.

7. There should be sufficient space for the drying of scenery, costumes, and properties the morning after a rain.

8. A bulletin board for nightly directions to actors and technicians should be set up in a free and convenient spot, a little away from any of the main traffic lanes onto the stage.

9. There should be an efficient intercommunication system over which messages can be sent from one side of the stage to the other, from the stage manager to the electrician, the organist, and the house manager.

The area behind the main stage should not be used for any large operation. There should be no lighting here except what may be planned for stage effects, and all trees should be left standing to maintain a good background screening for the stage pictures.

A spacious passageway should be provided for the actors and technicians who have to cross behind stage from one wing to the other.

THE DRESSING ROOMS

The placement and size of the dressing rooms will depend to a great extent on local topography and on the number of actors in the show.

The dressing rooms should be put as near the wings as possible without interfering in any way with the backstage movement of scenery and actors.

At the same time, the dressing rooms should be completely out of view of the audience. Care should be taken to see that no light shining through a door or window finds its way directly or indirectly to the eyes of the spectator, and that noises in the dressing rooms are not heard out front.

The dressing rooms may be laid out as a group of small units to take care of small groups of actors, or as larger rooms capable of taking care of big groups of men or women.

The best arrangement has smaller dressing rooms for selected groups of male and female actors; one for the leading men, one for female leaders, and other rooms for groups of secondary players.

If there are any in the show who have to use unusual makeup, like Indian body wash and war paint, these should be given an area partitioned off so that their body makeup will not

rub against other actors' costumes. They should have also their own shower facilities.

A shelf-type makeup table of 18 in. width and 30 in. height should be built around the walls of the dressing rooms with a 2 ft 6 in. or 3-ft space for each actor. In front of each actor will be a makeup mirror with a 75-watt light on each side. Benches or chairs 18 in. high, sufficient for all of the makeup positions, should be provided.

Ample space and equipment should be furnished each member of the cast for dressing and for the hanging of costumes, especially if they are of period design. Some permanent costume racks are recommended.

It is desirable to have at least one full-length mirror in each dressing room.

Showers, lavatories and toilet facilities must be supplied for each large dressing room or dressing room area. There should be at least:

- One toilet for each six persons
- One shower to each six persons
- One wash basin for each four persons
- Several urinals for men
- More toilets for women

If the production has only a few actors who use body makeup, the need will be for fewer showers and more wash basins.

Hot and cold running water must be furnished. It will be needed by the actors in the evening and by the costumer during the day. The hot water heater must be large enough to furnish hot water to a large number of actors in a short space of time. There might be one 400-gal heater or two 200-gal heaters, one for each side. Oil, coal, or gas heaters are better than electric since the electric require a longer warming-up period than can usually be tolerated.

The dressing rooms must be properly ventilated. Louvers and large circulating fans are suggested. Windows, if used, should be placed away from the stage and the audience area to minimize light leaks.

Light baffles for doors can be used to avoid these leaks. The doors should be placed in such a way as to be of convenience to the actors wanting to reach the backstage areas, while keeping to a minimum the danger of light spills.

SHOPS AND OFFICES

The Costume Shop

The shop should be conveniently close to the dressing room area. The size of it and the equipment of it will depend on whether it is to be used simply for the maintenance or also for the preparation of costumes. If it is to serve as the main construction center it should contain space for a large cutting table (about 3 by 6 ft) and at least four sewing machines, sewing tables, and chairs. The shop must be large enough to house one or more washing machines. It should also have space for the storing of materials and accessories. The shop should be at least 30 by 30 ft. It would be wise for the architect to consult the costumer before the final plans for this room are drawn.

The costume shop should be weatherproofed and well ventilated to prevent mildewing of the costumes in damp weather. If the shop is to be used as the winter costume storage room, it will require a more carefully constructed building than one used only in the summer months.

Very important is an indoor drying room for the rapid drying of laundered costumes on

AMPHITHEATERS

rainy days, and the drying of suits and dresses caught in summer showers during a performance.

The costume room should be well lighted by fluorescent lamps.

The Scene Shop

The scene shop should be located in the back-stage area, and it should not be in view of the audience. Unless it is to be used also for the nightly storage of scenery it does not necessarily have to be immediately adjacent to the stage areas. However, it should be built for the convenient removal of built and painted scenery and properties from the shop to the stage. It is very important that the building be weatherproofed, and that it be large enough and of proper height for the construction and painting of all shapes of scenery. It is well to consider the width and the height of the doors, since the completed scenery unit may be rather high and wide and will therefore require an opening large enough to permit its being carried out easily.

The size of the scene shop should be at least 30 ft long by 30 ft wide by 20 ft high. It must be long and wide enough for the construction of a big two- or three-fold flat. The scene shop must be high enough to allow a 16-ft flat to be moved around easily in an erect position. There should be large doors at the end of the building most convenient to the stage. The doors should be at least 12 ft wide by 9 ft high.

The shop should be well ventilated to speed the drying of the freshly painted scenery and make the technical crew comfortable while working in hot weather.

The shop should be well lighted, preferably by fluorescent lamps.

It should be equipped with hot and cold running water. A shower would be desirable.

Desirable is an outdoor space for the building and painting of scenery and properties during periods of good weather.

There should be a weathertight storage room for the preservation of the scenery and properties during the winter months. Precaution should be taken to prevent damage by rats. (Sacks of "Warfarin" or other rodent repellents may be placed around both the scenery and costume storerooms.)

Offices

It is desirable to have backstage office space

for the director, technical director, lighting director, choir director, and stage manager. The stage manager should have at least desk space. The costumer and technical director can use a section of their costume and scene shops respectively as offices.

LIGHTING TOWERS AND OTHER LIGHTING STATIONS

A special problem which will come into the architect's planning is that concerned with the design of the lighting for the three stages. This should be worked out carefully in consultation with a lighting expert.

The first part of the problem involves the shape, size and placement of the two lighting towers (for front illumination of the acting areas) on each side of the auditorium. They should be close enough to the main stage to provide it with maximum spotlighting, far enough in — toward the center of the auditorium — to make the angling of the light lines to the corners of this stage effective. At the same time the towers should be far enough up the hill away from the side stages to permit getting good illumination down onto them. (Some of the spotlighting for each stage will come from the rear tower, some from across the auditorium from the tower on the other side.) Each tower should be high enough to let the light fall on the rear side stage at an angle of about 45°, illuminating clearly figures on that stage without spilling light onto the main stage beyond. If the side stage extends 30 ft out from the proscenium wall and the tower is placed about 15 or 20 ft up the hill from this — that is, 45 or 50 ft from the proscenium wall — the tower may have to rise 30 or 35 ft above the level of the main stage.

At least two banks of large spotlights will be hung in the top of each tower. In the bottom of one tower might be placed the control board for all stage lighting, and in the bottom of the other the console of the electric organ, together with the control of any sound equipment (such as that for a narrator) that may be employed in the play. Some theaters use space below the lighting towers for rest rooms for the audience, after providing separate access for the lighting crew.

While the towers are being placed for effective illumination, they must be arranged in such a way as not to interfere with the sight lines

from the rear side corners of the auditorium to the acting areas on the side stages. In order to keep the sight lines clear, the architect will have to put the towers closely contiguous to the side aisles, and he may have to modify the width of the auditorium at the back.

Some of the smaller and newer theaters, concentrating on use of the Quartz-Iodine lamped long-throw spotlights, have minimized the use of lighting towers by mounting a battery of spotlights on top of the rain shelter at the rear of the audience. A few years ago the spotlight cost would have been too great, but new lens systems developed for quartz lights now allow this type of mounting as an increasingly popular solution for lighting both main and side stages. At present most theaters still use lighting towers as well as the newer rain-shelter mounting.

Other stations for stage lighting will be on pipe framing just behind the edge of the proscenium walls on both sides, and in narrow foot-light troughs at the front edges of the main and side stages. The play will doubtless require additional incidental stations, but since these will probably be on or behind scenery units they will not involve the architect.

All permanent wiring which is to be run in conduits under the ground from the towers to the stages, between the towers and between the stages, and to controls, should be laid before any paving is done.

LIGHTING CONTROL EQUIPMENT

The lighting control booth should allow the operator full vision of all acting areas which are to be lighted. The best location in the 1,500–2,000 seat theater is above the rain shelter high over the rear of the audience.

Some theaters use a booth built in the center of the auditorium, but this causes a loss of valuable revenue seats. Others use space in the ticket office building, or space at the base of one of the lighting towers.

Location of lighting control consoles backstage is considered old fashioned and inefficient.

Many good lighting control systems are on the market and a number of them should be investigated to determine the best possible choice for your production situation. A minimum of 85,000 to 100,000 watts will be required in any standard situation.

ROOM AND AREA REQUIREMENTS

Music facilities can be divided into two general classifications depending upon their function: those used for instructional activities and those serving in an auxiliary capacity such as storage areas, workrooms, and offices. A typical large music facility for an institution of higher education will require a wide variety of rooms and work areas. The needs of elementary and secondary schools will probably be somewhat less but will incorporate many of these functional areas. (See Fig. 1.)

1. Instructional areas

- Rehearsal halls
- Practice rooms
- Class piano rooms
- Regular classrooms
- Listening facilities
- Studios
- Recital hall
- Combinations

2. Auxiliary areas

- Storage areas
- Music library
- Work rooms
- Broadcast control booth
- Additional facilities

Instructional Areas

Rehearsal Halls—Instrumental Rooms An instrumental rehearsal room obviously should be large enough to accommodate the largest band, orchestra, or combined group expected to use the facility. The needs may vary from one section of the country to another, but 80 to 120 pupils may be taken as the normal range. In some areas which emphasize large bands it is not unusual, however, to find groups containing up to 180 pupils. The use of the school for community music activities should also be considered. Combined school and community groups may make it desirable to construct somewhat larger rehearsal facilities and provide additional storage space.

Room Size. In estimating the approximate number of square feet of floor space that should be provided for instrumental groups, one should allow 20 to 24 sq ft per student (i.e., 1,600 to 1,920 sq ft of floor space for an 80-piece band or a 60-piece orchestra). This will provide the necessary space for aisles, music stands, and other equipment. No student should sit against a wall or stand within 7½ ft of the ceiling. This is especially true of the basses and percussion instruments, which are frequently placed on the highest riser in the back of the ensemble.

Room Height. The height of an instrumental rehearsal hall depends on the number of students involved as well as the shape of the room. One of the common faults of music facilities is the lack of sufficient ceiling height. Ceiling height must be planned for acoustic purposes even if a split-level effect is created

on the floor above the music suite. Not all such rooms will be designed with a ceiling that is parallel to the floor, so that an average ceiling height figure may be more meaningful than a simple number. This average will be in the neighborhood of 14 to 18 ft. Anything less than a 14-ft ceiling in an instrumental rehearsal room should be questioned. Another check to ensure adequate space for proper acoustics in a rehearsal room is to allow approximately 400 cu ft per performer.

Risers. Differences of opinion will be found concerning the desirability of providing risers in instrumental rooms. Pupils sitting in the back of the room and the far sides may have some difficulty in seeing the conductor unless they are seated on an elevation of some sort. No decided preference for flat floors or for risers has been demonstrated. Architects are currently designing music rooms of both types according to the preference of those planning the facilities. Whichever is used, flat floors or risers, it will be necessary to make the appropriate adjustments to provide for diffusion of sound. With the use of risers, additional room height will be needed. Some schools feel that semipermanent or portable risers solve the problem and provide room flexibility. The provision of sets of risers—one to be kept in the auditorium and another for the rehearsal hall—avoids some of the logistical problems, but many directors who have risers in the rehearsal room find the flat floor of the stage satisfactory. Many symphony orchestras have abandoned the use of risers, their conductors having discovered that when the brass and percussion sections are elevated, they often overbalance the strings. This may be even more true with school orchestras. The problem presented by the lack of stage enclosures (shells) far outweighs the problem of whether or not to use risers on the stage. Risers that telescope into the wall are another possibility, but the expense involved may prohibit their use in many situations.

If risers are used, a width of 60 in. for most terraces will prove adequate. A 60-in. step will be wide enough for a single row of instrumentalists or two rows of singers. The top riser should be wider (up to 120 in.) since the back of the room ordinarily accommodates the larger percussion and bass instruments. Ordinarily, an elevation of 6 to 8 in. is adequate (sight line is a good indication of ear line). A white strip of paint or a rubberized nonskid tread on the edge of all risers provides an element of safety. The number of terraces will range from one to five, depending on the size of the room and the needs of the organizations using the rehearsal facilities.

Other Considerations. The instrumental rehearsal room will probably be used for instrumental classes and possibly even for theory or other music classes. Mounted chalkboards are therefore desirable. Since rehearsing is the room's principal function, however, no decision should be made that will detract from its ability to fulfill that role. The straight chairs required for performing groups should not be sacrificed for tablet armchairs. Provisions for closed-circuit television and a projection screen should be considered. Many rehearsal rooms being currently planned and

built incorporate microphone outlets with adequate wiring leading to the control room.

If the room is to be used for orchestra rehearsals or cello classes, some thought should be given to the effect of cello end pins on tile or wood flooring. One solution is to provide for ½-in. plywood floor panels large enough to serve the player and his instrument.

Finally, it should be noted that there is some doubt as to the advisability of bands and orchestras using the same rooms. Recent research has indicated that, for teaching purposes, the band requires a much less reverberant room than does the orchestra.

Rehearsal Halls—Choral Rooms The specialized requirements of choral rehearsal rooms are somewhat different from those of facilities used exclusively for instrumental groups. Space requirements are simplified since it is not necessary to provide floor area for music stands and instruments. If the vocal groups are to stand for rehearsals, 6 sq ft per pupil will suffice. The use of fixed chairs on risers will require more space; at least 10 sq ft is necessary for each pupil if the risers are the minimum width of 30 in. Extra space should be planned if wider (36- or 40-in.) risers are preferred, 15 to 18 sq ft per person being not unusual. Choral room ceilings do not need to be as high as those in instrumental rehearsal halls, but should be higher than those in an ordinary classroom.

Risers. Few if any large choral groups rehearse or perform without the use of risers. They are used to avoid having the tone of singers in the back rows obstructed by the bodies of the singers in front. They are also essential for easy observation of the conductor. An elevation of 6 to 10 in. and a width of 40 in. are adequate for permanent or semipermanent choral risers.

Few choral directors desire an aisle in the center of the room. This may be avoided if the width of the riser and the distance between seat rows are sufficient to allow convenient passage. Safety regulations differ, but risers 40 in. wide are adequate to meet the requirements in most areas.

Since the choral room is most likely to be used as a general classroom in nonchoral hours, folding tablet armchairs will be useful for both classroom and rehearsal functions. Fixed opera (theater) chairs are sometimes employed in choral rooms, especially when the room is designed to serve as a recital hall. In all probability choral directors will want to make recommendations concerning the chairs to ensure proper support for the lower back of the singers. Not less than 125 cu ft of space per seat should be provided in recital hall-choral rooms.

Some choir directors prefer to have their groups stand for rehearsals as well as for concerts. In such cases the risers should have a width of approximately 15 in. and a height of 8 or 10 in. per step. A permanent or portable stage is an advantage for a choral room. Three or four steps from the floor of the room to the stage can be designed to serve as permanent standing risers.

Other Considerations. The use of the choral room for other than rehearsal functions

suggests the advisability of providing chalkboards, a projection screen, and closed circuit television. Microphone outlets for recording and broadcasting should be considered. Schools being built now should be planned to make possible the use of performing groups for broadening the cultural life of the whole school.

Rehearsal Halls—Combined Vocal-Instrumental Facilities Let it be said at the outset that acoustically, one room cannot serve for both vocal and instrumental rehearsals with completely satisfactory results. Some communities, however, find it economically unsound to provide space for both instrumental and vocal groups while employing only one teacher. It is therefore expedient to consider space for the combined vocal-instrumental situations. Provisions for changing the reverberation characteristics of such a room with drapes or other materials are a possibility.

In many one-teacher situations, one room is the nucleus of all music activities. In the small-

est of music departments, a single all-purpose room can be planned in terms of space to accommodate the vocal and instrumental group rehearsals, small ensembles and individual rehearsals, library, instrument and equipment storage, instrument repair facilities, office, and teaching studio as well as various other music classes insofar as the scheduled school day permits. Although space can be provided for this multipurpose situation, few of these activities can be adequately housed in one room without creating undesirable acoustical

conditions for the other activities. It may be dangerous to ask elementary school children and the majority of junior high school pupils to sing in such compromise situations. While variable acoustical control may be employed, the installation of such materials may be more expensive than providing additional facilities. When possible, separate special rooms for instrumental and choral activities should be provided, since vocal groups require a much "warmer" room than do bands and orchestras.

Space in such a combination room will have to be figured on the basis of the suggestions made for instrumental rehearsal halls. The room might be thought of as the future instrumental room, expansion to separate facilities being the ultimate goal.

Practice Rooms Practice rooms are a facility peculiar to the teaching of music, with some special problems not encountered by administrators or architects in planning other elements of the school. Among the factors which must be considered are isolation of sound, size, ventilation, amount of use, and supervision.

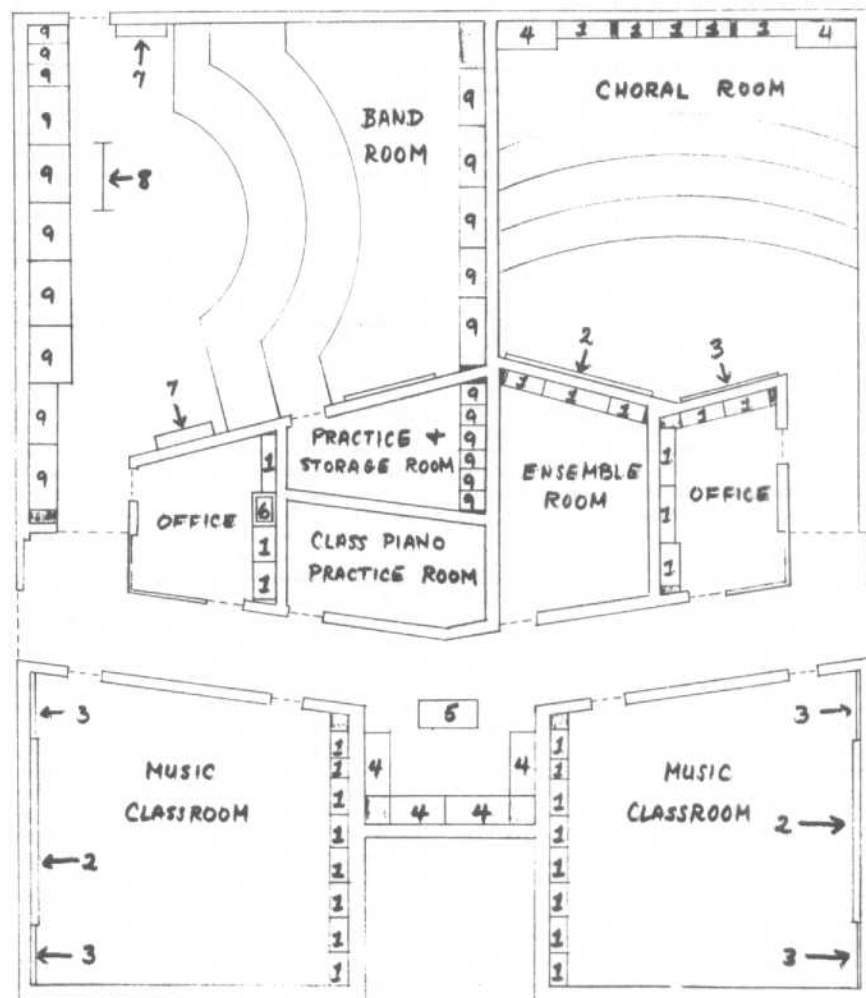

Number. The number of practice rooms needed by a music department should be related to the number of students involved and the administrative policies concerned with their use rather than by the amount of space created by the architect in splashing the back wall of the rehearsal hall. Some authorities recommend that students practice as much as possible in school, so that assistance and supervision are possible. Many feel that it is particularly important that practice room facilities are available for those students who play the larger instruments because of the difficulty in carrying the instruments home. These practice rooms should be convenient to the large rehearsal room, so that the moving of heavy, large instruments is minimized. In determining the number of practice rooms needed by a collegiate school or department of music, a calculation similar to that shown at the top of the page might be used.

Size. Practice rooms vary in size according to their various functions. Individual practice rooms are quite satisfactory in the 55 to 65 sq ft range. This provides sufficient space for an upright piano, a chair, and a music stand—but little more. Public schools, once planned with several rooms of this size in the music suite, are now being built with slightly larger rooms for ensemble practice, reflecting the increased emphasis on small groups, both vocal and instrumental. Colleges which plan large blocks of small practice rooms will also want to provide a number of larger rooms for ensemble practice, or to accommodate grand pianos (2) or organs.

Other Considerations. More and more school buildings in the North as well as the South are being air-conditioned, and this is a distinct advantage where practice rooms are concerned. In fact, there is no other way to provide proper sound isolation. If the building is air-conditioned, the practice rooms can be arranged in blocks, spaced compactly, and planned without outside windows. Sound filters should be provided for the air ducts to

50 music majors	×	16 hr per week =	800 hr per week
40 on secondary instruments	×	6 hr per week =	240 hr per week
80 theory students	×	2 hr per week =	160 hr per week
150 elementary education students	×	2 hr per week =	300 hr per week
			1,500 hr per week

$$\frac{\text{Practice hours per week}}{\text{Hours available for use per week}} = \frac{1,500}{60} = 25 \text{ practice rooms needed}$$

MUSIC FACILITIES

prevent transmission of sound from one room to another, and the return air ducts should be placed in the ceilings or walls, not in the doors. Construction to ensure adequate transmission loss will make practice rooms more expensive than ordinary classrooms, but economies may be effected here with more justification than in some other parts of the music suite.

Nonparallel walls have been widely used to avoid reflection of sound in these small rooms. Double glass windows in the doors, or opening on the rehearsal hall or teacher's office in schools, permit supervision without interruption. Electronic monitoring devices are sometimes incorporated.

Class Piano Rooms Many school systems are now providing class instruction in piano as well as in the band and orchestra instruments. Some schools have constructed specially designed rooms for this type of instruction. These rooms should be as near as possible to the other music rooms in order to realize complete utilization in a coordinated music program. There should be acoustical treatment of the walls and ceilings, and insulation against sound transmission to and from other classrooms as prescribed by the acoustical consultant. Careful consideration should be given to sound conditioning of rooms for class piano if several pianos are used, due to the percussive action of tone production of several performers. The front wall should be equipped with blackboard (plain and with music staves), bulletin board space, music cabinet, and electrical outlets. Space should be provided for television, phonograph, and recording facilities.

If electronic pianos are used in such a room, it is useful to provide an adequate number of electric outlets in the floor to avoid the need for extension cords and the hazard they present. Organ class instruction is now finding increasing favor in several of our larger cities, and properly wired rooms should be planned if this activity is to be part of a school's program.

Regular Classrooms Regular academic classrooms are used by many schools for classes in music history, appreciation, theory, composition, arranging, and other music education classes. Though the acoustical treatment may not need to be as extensive or expensive as in some other parts of the music suite, if the learning to take place in the room is to involve listening to music, more than ordinary care must be taken to block out extraneous sounds. A classroom that will be used primarily for general music classes needs ample storage space for books, records, rhythm instruments, autoharps, piano keyboards, pictures, and similar equipment. Provision should be made for a projector screen mounted at ceiling height or in a ceiling recess.

In some situations it may be possible to provide a projection room adjoining the classroom, or even between two classrooms so that the projector can be prepared without losing class time. If a classroom is to be used primarily for theory classes, it will be desirable to have staff lines painted on the chalkboard. Conversely, if music literature classes are to be the principal occupants, painted staff lines are less desirable. If a college classroom is to be used largely for music education classes, it will need adequate locked shelf space or will need to be planned adjacent to a storage room (with shelves) for the large amount of material used in such classes. In a campus school situation, classrooms may need to be provided with rows of coat hooks and shelf space.

Listening Facilities Several types of listening facilities are in common use in collegiate music

schools today, and each presents specific planning problems. As independent study becomes more common in secondary schools, some similar facilities will become desirable in the music department or in the school library. The principal systems include the following:

1. A number of soundproofed listening rooms or cubicles are each provided with a record player. The student receives phono recordings from a central location (often the departmental office) and is his own operator.

2. A bank of record players or turntables is placed in a central control room. Worktables in an adjoining room are supplied with a number of receiving channels and sets of earphones. The student requests a particular recording, which is played by the monitor in charge of the control room, and the student listens through earphones.

3. Tapes are made available to the student, who listens either in a cubicle as in (1) above, or in a central room (in which earphones are necessary).

4. Tapes are administered through a control room, as in (2) above, and the student listens through earphones.

The planning of a listening facility is dictated first of all by the kind of equipment the department uses, or the kind to which it wishes to change. The number of listening rooms or cubicles, the size of the control room and the number of channels available, the number of places at the worktables can be calculated by a method similar to that employed in the case of practice rooms. The design of the system, if methods (2) or (4) are used, must of course precede the planning of the area. Other than providing for adequate space and convenient location in relationship to other music areas, no general observations will be needed in this section.

In many cases a college will set aside certain classrooms as theory laboratories. It may be desirable to provide cubicles in which students may work with individual tape recorders, phono records, or similar equipment. Certain storage and control requirements must also be planned in such situations.

Studios Traditionally much of the teaching of music has been done on a one-to-one basis. Though this country has accomplished much through group instruction, it is still true that advanced instruction is almost always given to a single student. In colleges and conservatories this is carried on in studios which also serve as the faculty members' offices. It is desirable also for schools to provide an office for each full-time music instructor. Most frequently it is located adjacent to the teacher's rehearsal hall and is provided with windows that enable him to keep an eye on ensemble rehearsals being conducted by students in the hall or in practice rooms.

In a college it is not difficult to determine the proper number of office-studios, since the figure corresponds directly with the number of applied music teachers. More difficult is the matter of assuring the responsible authorities that space devoted to the studios will be fully used. A college instructor teaching applied music is likely to have a teaching schedule of 18 to 24 hours per week, and he will wish to do his own practicing and professional work in his studio. Occupancy of somewhere between 30 and 40 hours per week may thus be expected. Administrators may expect a 50 to 60 hour-per-week occupancy as they do in the case of classrooms and practice rooms. They may need help to see that an applied-music teacher cannot work effectively if he has to share a studio.

Size. The music teacher's office needs to be

larger than a small practice room since he will, in all probability, have his desk and files there. There should be enough additional space for group lessons if he has the need. Music files, instrument storage, and work areas frequented by students should not be in the office-studio.

College studios will vary in size with the instructor's specialty. Studios of the senior piano staff will ideally be large enough to accommodate two grand pianos and the usual office furniture of desk, file cabinets, and bookshelves. Studios of instructors of voice and other instruments, traditionally requiring only one piano, can be a bit smaller if acoustic conditions are otherwise met. Nonparallel walls are recommended, but the studio should not be designed in such a way that piano placement and disposition of furniture are made difficult.

The size of the studio may also be determined by other duties of the faculty member. As an academic adviser, he may need additional space for file cabinets; if he uses the room for seminars he may require space for a table and chairs. In virtually all cases a small mounted chalkboard in each studio will be a valuable asset.

Recital Hall A room intended for recitals or for performances by chamber music groups or small ensembles may be termed a recital hall. Anything larger falls into the category of theater or auditorium. Thus, planning the recital hall may well begin with a decision about the hall's intended use and its seating capacity. This will in turn influence the size of its stage and bring about certain limitations of use. A hall seating 250 people, say, can scarcely have a stage large enough to seat an orchestra and chorus, or even a large band. Schools may combine the idea of a recital hall or little theater with the need for areas for large-group instruction.

As in the case of other large special-use rooms, one may think of a recital hall as including several subareas also. Chief among these are performers' dressing room or rooms, pipe-organ chambers (if the hall is to have an organ), recording or broadcasting control room, and box office. In each case, the location of these subareas should be considered in relation to ease of concert operation. For example, a control room should have a view of the entire stage, and performers' rooms should be located on the same floor as the stage rather than a floor above or below; otherwise both lose much of their convenience.

The seating capacity of the recital hall having been determined, its shape, proportions, etc., become matters for the architect. But a number of practical considerations, often overlooked even by experienced architects, may be listed here. For example, the lighting panel or dimmer panel should be located on the same side of the stage as the dressing room, for that is the side at which the stage manager will normally stand in order to communicate with the performers. A bell or phone system should connect the backstage area with the box office, for efficiency in concert operation. Doors leading from the wings onto the stage must be wide enough to provide for the passage of a grand piano—a small detail, yet one that has often been missed. If delivery of pianos or other large equipment is anticipated, the stage should have access to a loading dock. And even if the music building caters primarily to campus audiences, provision for parking areas should be considered.

Even at the college level, the recital hall, as in the case of the large rehearsal rooms, will probably double as a classroom or large lecture hall at certain times. It may be necessary, therefore, to provide theater-type seats with folding tablet arms so that the needs of both concert

audience and note-taking students may be met. A large ceiling-mounted projection screen may be found desirable, as well as connections to the recording studio. Some thought should be given to the location of a projector, since a special projection booth is unlikely in a small recital hall.

Fine Arts Combinations Many schools are adopting the administrative policy of establishing fine arts departments and housing art, drama, and music in units separate from the classroom area. Buildings of this nature usually consist of a music complex, a drama complex, and a visual arts complex. Dance may sometimes be included (see Fig. 2).

The music complex has been described earlier. The drama complex consists of a small theater with a capacity of 300 to 500, workroom, dressing areas, one or more classrooms, storage rooms, radio-television control and listening areas, costume storage and work area, and library.

Auxiliary Areas

Storage Areas Adequate storage areas, planned with traffic patterns in mind, are important to the proper functioning of a music facility. Storage, with proper heat and humidity control, is necessary for musical instruments, robes and uniforms, music, records, and various types of equipment. With careful planning, the

storage areas can be conveniently placed and at the same time serve as a buffer between two sound-producing areas such as the instrumental and choral rehearsal halls (see Fig. 3).

Instrument Storage. Instrument storage facilities should be located so as to minimize the moving of instruments. Sufficient free floor space should be provided to permit smooth flow of traffic. Storage cabinets located within the rehearsal areas are inaccessible during rehearsal periods and frequently cause congestion during period changes.

Uniform and Robe Storage. Storage facilities should be planned for the school-owned band and orchestra uniforms, choir robes, or vestments. This closet space should be cedar-lined. A well-constructed, close-fitting door will help protect against moths and dust. The closet space should be high enough so that the uniforms and robes will not touch the floor when hanging on the racks. Some provision should be made to space the uniforms and robes at equal intervals and to facilitate identification. A separate (pigeonhole) compartment for the caps, belts, and other miscellaneous equipment should also be provided.

Music Library Music libraries will range from a single set of filing cabinets in the music room to the school of music library complete with stacks, reading rooms, charging desk, listening facilities, and work areas. In most colleges there will also be smaller libraries (band,

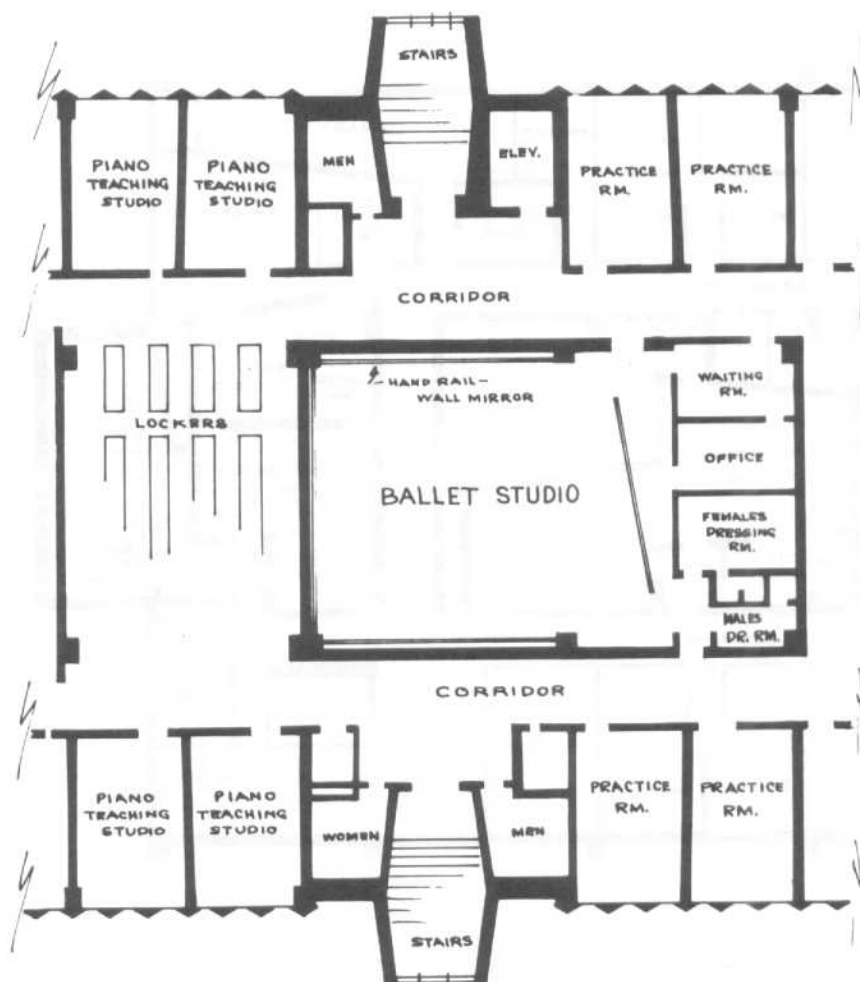

Fig. 2 Provisions for instruction in dance may be included in some buildings. College Conservatory of Music, University of Cincinnati. Edward J. Schulte and Associates, Architects.

Fig. 3 Plan for a two-teacher music department.

orchestra, choral) which are more like the school situations described here.

Workrooms Instrument Repair. Some sort of facility should be provided for emergency instrument repairs. A special room is recommended, although many schools will use a section of the music library room or director's office for this purpose. Larger school systems will employ specially trained men to take care of all instrument and equipment repairs. The minimum provision should be a workbench, stool, and a supply of tools for repairs. Cabinet

MUSIC FACILITIES

space with small drawers should be provided to hold pads, pad cement, springs, cork, and other miscellaneous equipment. If a great deal of repair work is done in the school, the workbench should have a gas connection, electrical outlets, wood and steel vises, and other specialized equipment. Running water and a large sink for cleaning brass instruments should be included.

Duplicating Room. School music departments will have the facilities of the general office at their disposal in most cases and may not need duplicating equipment in the music suite itself. Most collegiate departments or schools of music and some school departments housed separately in a campus-type school will find a duplicating room invaluable. There are many times when the music department needs items copied—rehearsal schedules, instrumental parts of a student composition, football show routines, trip itineraries, vocalizes for the choir, songs in the public domain—that equipment should be readily available. The room should include enough counter space for several types of machines, space for collating, and a sink.

Offices. A music program that functions smoothly should provide a well-located director's office. The size of the office and the types of equipment included in it will depend on the size and organization of the school. The room need not be especially large unless it is also to serve as a studio in which small-group

instruction may be carried on. It should, however, be able to accommodate a desk, two or three chairs, filing cabinets for correspondence, cabinets for miscellaneous storage, and any special equipment such as electronic tuners, piano, phonograph, radio, and tape recorder.

Music teachers who teach in several locations in a school (e.g., harmony in a classroom, choir in the recital hall, general music in a specially equipped center) need an office to organize the many materials and instruments and pieces of equipment with which they work. Offices are also essential for the department head or the director of performing groups because of the frequent contact they have with members of the community.

Broadcast Control Booth The recent improvements in recording equipment and television education have resulted in many schools being constructed with facilities to make possible the use of these new techniques. Educational programs of all types are made available to the school and community; therefore, school space should be allowed for both receiving and broadcasting of music. The control booth should be well insulated for sound and should have slanted double glass windows for viewing the performing groups. Such a control booth is sometimes located adjacent to the stage of the auditorium or recital hall and sometimes between the rehearsal halls. (See Fig. 4.)

Additional Facilities *Washroom and Toilet Facilities.* Because the music suite is frequently used at night when the remainder of the building is locked, washroom, toilet facilities, and custodial work areas must be provided within the music unit. In many instances they may be necessary for the changing of uniforms and must be convenient to the rest of the department. These facilities require about 15 percent of the total floor space if adequate room is to be provided. If recitals to which the public is invited are given within the music unit, additional rest room space may be needed.

Lounge. Collegiate music departments may need to consider the desirability of a lounge in which students can relax. If other study areas on the campus are some distance from the music facilities, one portion of the lounge might provide desk or table space. An area might also be provided for vending machines.

Elevator. Because of the heavy instruments and equipment which it is frequently necessary to move in a music department, an elevator is a most desirable feature in a building of two or more floors. Also recommended is a loading dock adjacent to the parking area.

THE AUDITORIUM

An auditorium should be designed so that the activities can be maintained and operated with a minimum of time and labor consumed in the

Fig. 4 The recent improvements in recording equipment and television education have resulted in facilities to make use of these new techniques. College Conservatory of Music, University of Cincinnati, Edward J. Schulte and Associates, Architects.

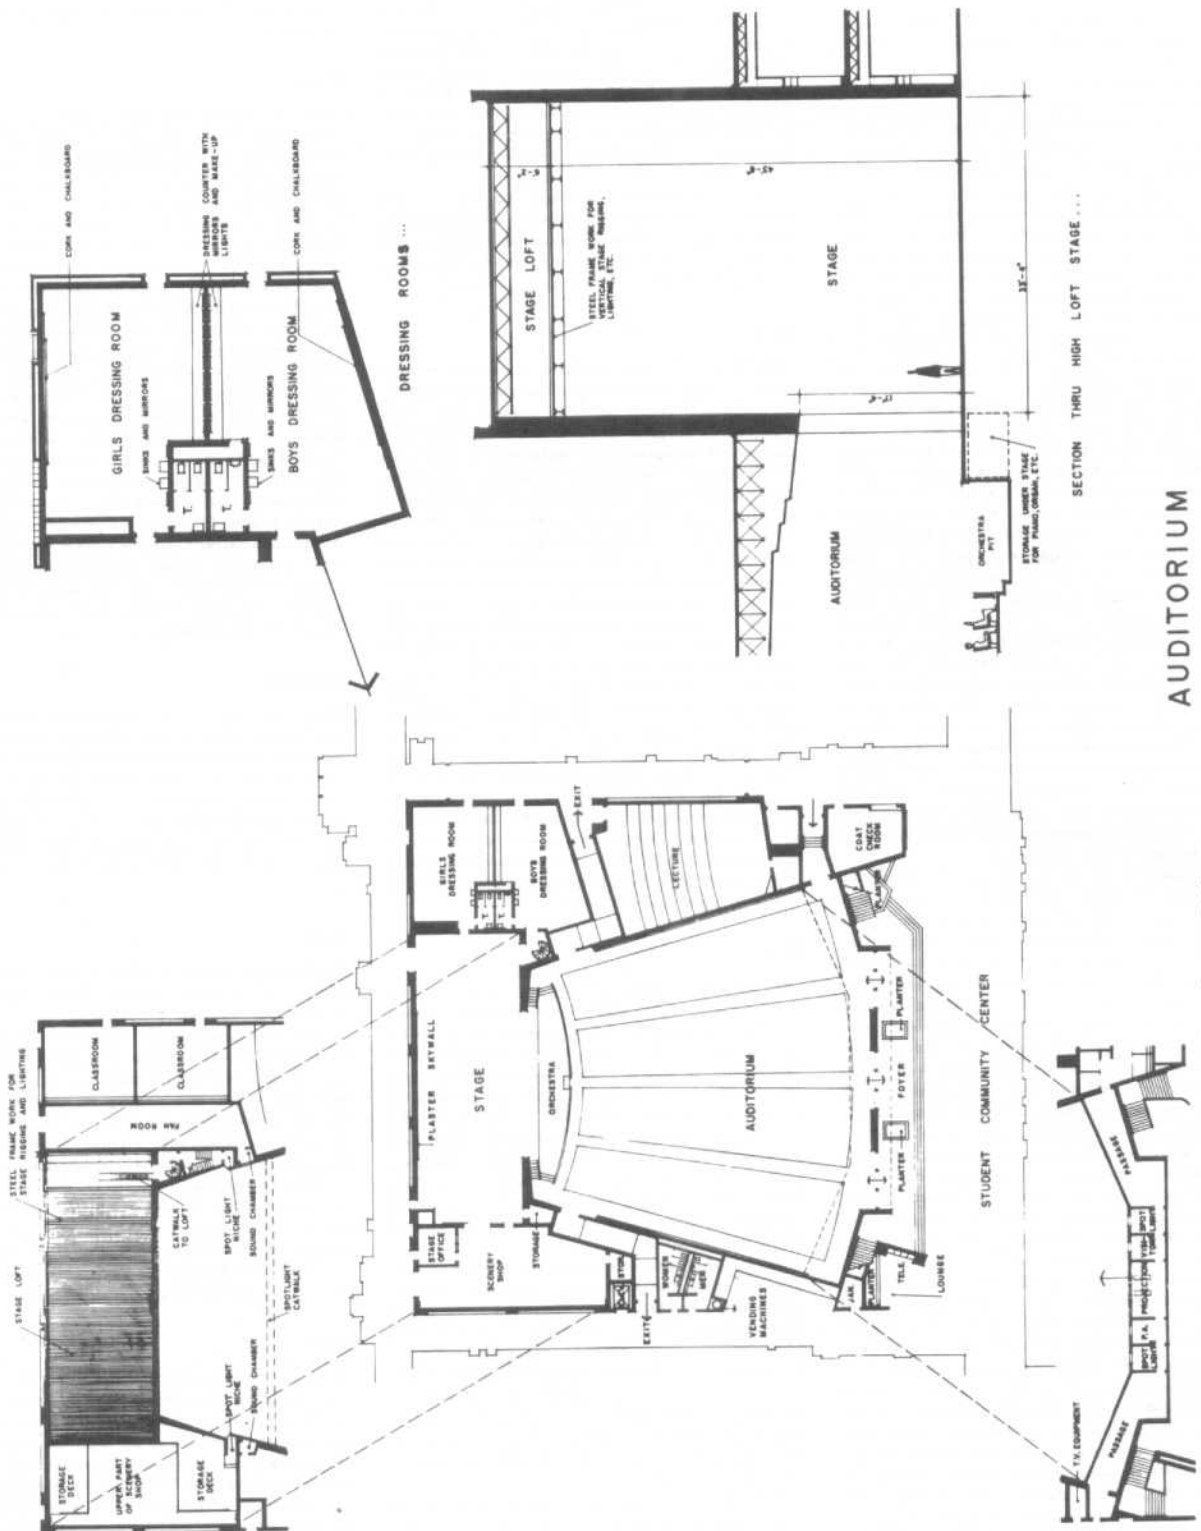

Fig. 5 North Central High School, Indianapolis, Ind. Everett I. Brown Company, Architects.

preparation of an event. In schools, this area is being designed for education, not commercial purposes.

Stage

The stage is considered first because it is the part of the auditorium most frequently abused by the designers.

The proscenium arch size is dependent upon several factors—the size of the auditorium, the playing area of the stage, the height of the stage loft or grid (Fig. 5), the size of the community using the auditorium, and the seating capacity of the auditorium. For general purposes, the proscenium arch should not exceed 65 or 70 ft in width and the height of the auditorium should be in practical or artistic proportion to the width. This height is an important factor that will determine the location of the grid. The grid will be the subject of a separate discussion. All of these items are interrelated, and the architect must consider all of them and their interrelationships.

The playing size of the stage will be determined by the sizes of the musical organizations, the stage requirements of musical or dramatic productions, and the scope of other activities proposed for this stage. Clarence J. Best recommended in his survey that an orchestra player be allotted 18 sq ft of floor space for himself, his instrument, and his music stand. This is a generally accepted figure for the minimum seating area and is much less than recommended for the rehearsal hall, because the space needed at the front of such a room need not be figured here. A 100-piece orchestra would require about 1,800 sq ft of floor space, or an area about 50 ft wide and 36 ft deep. For practical purposes the requirements for band are about the same. The stage will have to be proportionately larger if the instructor is planning to rehearse and use combined choral and orchestral groups. This is the type of information the music educator must supply to the architect.

The stage area of 1,800 sq ft mentioned above merely refers to that part of the stage visible to the audience and usable inside the shell or legs. The offstage area is often overlooked, yet it is a very important functional part of the stage. In presenting concerts, operettas, and plays, some offstage area is necessary to handle personnel, scenery, and equipment. These areas are often too small. The left and right offstage areas should each be approximately one-half the size of the stage plus 10 percent. In addition, there must also be sufficient offstage area for the pin rail, switchboard, and similar permanent features. A large proscenium opening can always be made smaller through the use of curtains, flats, teasers, etc. If the major architectural construction is too small, increasing the size of the proscenium is very difficult.

A good proportion to follow in determining the depth of the stage is that the depth should be 75 percent of the width of the proscenium arch, and this depth area should continue on both sides of the stage. To use simple figures, if the proscenium arch is 48 ft, the depth of the stage should be 36 ft. The offstage areas would be approximately 27 ft wide and plus that additional space necessary for permanent equipment on the right-hand side. Both offstage areas would be 36 ft deep. This offstage area could handle stage wagons that would cover the entire playing stage. It would be of sufficient size to store a number of stage sets for musical and dramatic performances. A trap in

the stage floor is handy for moving equipment from work areas below and makes possible special effects in dramatic productions.

The offstage areas should be readily accessible to adequate dressing room space. There should be adequate space close to the stage to take care of lighting machines, lighting cables, repair and supply parts, and storage for curtains and other stage equipment. In all educational situations it is practical to have the rehearsal rooms for chorus, orchestra, and band in close proximity to the stage in order to facilitate the preparation for rehearsals, concerts, and recitals.

The instrumental storage rooms, library rooms, scenic shops (including painting racks), and construction areas should be close enough so that properties can be shifted onto the stage with a minimum of effort and damage.

Apron

The floor area in front of the proscenium arch is called the stage apron. This apron should be at least 8 ft wide, so that pianos and other equipment may be used in front of the main curtain. The apron may extend out over the orchestra pit. The front of the apron should be finished with a hard oak or maple flooring, and that part in back of the proscenium should have close-grained pine in order that the floor will not splinter and yet will be soft enough to take stage screws. Much money has been wasted on hardwood floors for school stages, to the extreme exasperation of stage directors and their crews. The oak or maple floor should be finished with a high gloss but not waxed, and the pine floor should be finished with many coats of oil and the oil allowed to penetrate the wood thoroughly so that it will be fairly seasoned. On both sides of the stage leading from the auditorium to the stage apron there should be appropriate steps. These steps should be wide enough to enable personnel to carry musical instruments and other small properties to and from the auditorium to the stage, or so that the students may approach the stage at least two abreast.

Grid

One of the paramount faults of school auditoriums is that the grid over the stage is often not high enough to allow the scenery to be pulled out of sight. The grid should be at least the height of the proscenium arch times two plus a minimum of 8 ft. Then there should be from 4 to 7 ft above the grid to the top of the building structure, so that the people who find it necessary to work on the grid, changing pulleys, etc., will have sufficient room. The overall height must be sufficient to make it feasible to hang scenery and pull it out of sight in changing sets.

Often when there is no space overhead and scenery must be pulled into the wings of the stage there is also not enough space to stack this scenery offstage. Thus the only solution is to make the stage smaller, masking out with drapes or flats and reducing the proscenium arch so that the stage is much narrower. Then the stage crews will have to work behind the drapes as a backstage area. *If dramatic productions are anticipated, space should be provided for a grid.*

One not too familiar with stage operations or requirements often finds the grid an ideal place to run ventilating pipes, conduits, steam lines, and water pipes. Just because this large grid area presents a wide open space, it is a

tempting area for various trades; however, this area must be kept entirely free for the necessary stage equipment. Nothing is more distressing than to have guide ropes fouled among ventilating ducts, or to have steam pipes leak in the center of a stage set during a performance or concert.

Battens

A proper stage will have a number of battens suspended from the grid. These battens are long pieces of pipe extending the full width of the stage and continuing backstage, so the curtains and legs may be hung backstage in order to mask off this area from the view of the audience. Battens are part of the permanent fixtures of a stage. The common way to counterbalance the battens is through installation of a pin rail. The standard counterbalancing equipment as supplied by the major manufacturers of stage equipment is usually satisfactory. Make-shift installations should be avoided. Battens should be placed 6 in. apart. There never seem to be enough pipe battens to take care of the stage needs. All the lights, border lights, teasers, a border in front of each strip light, three or four legs on each side, the front curtain, oleo curtain, back drops, and sky drops are all standard pieces of equipment that are hung from battens. By the time a light batten or light bridge is added at the fore part of the stage and sufficient battens are provided for scenery changes, it is not at all unusual to use about 25 or 30 battens.

Cyclorama

Most stages require a cyclorama and a set of cyclorama lights. This cyclorama should not be taken as a substitute for a stage shell. A cyclorama is usually a continuous curtain starting close to the proscenium arch on one side of the stage. It extends to the rear of the stage, across the back of the stage, and comes forward, ending close to the other side of the proscenium arch.

Shell

Every stage must be equipped with an adequate shell. For lectures, concerts, and recitals on theater stages, the purpose of a shell is to project the sound into the auditorium. This shell should not attempt to use border lights for lighting but should have lights installed in each section of the ceiling so that the stage will be flooded with about 60 to 70 footcandles of lighting. The lights should be arranged so that the back row will have sufficient light, and so that the lights will not throw a glare back into the audience. The shell should be made the full width of the proscenium. The ceiling can hang from the battens. The size of the shell can be varied by adding or subtracting flats and adding or subtracting ceiling sections.

Doors

All doors entering on a stage must be of sufficient height and width to provide ready access to the stage. This is especially true of the scenery doors. They must be high enough to accommodate wide stage wagons, large instruments, and permit (if necessary) entrance of motor vehicles. The door for scenery should be at least 8 ft wide and 14 ft tall, and all other doors leading to and from the stage should be unusually wide double doors. Doors leading into the auditorium should be solid, with no

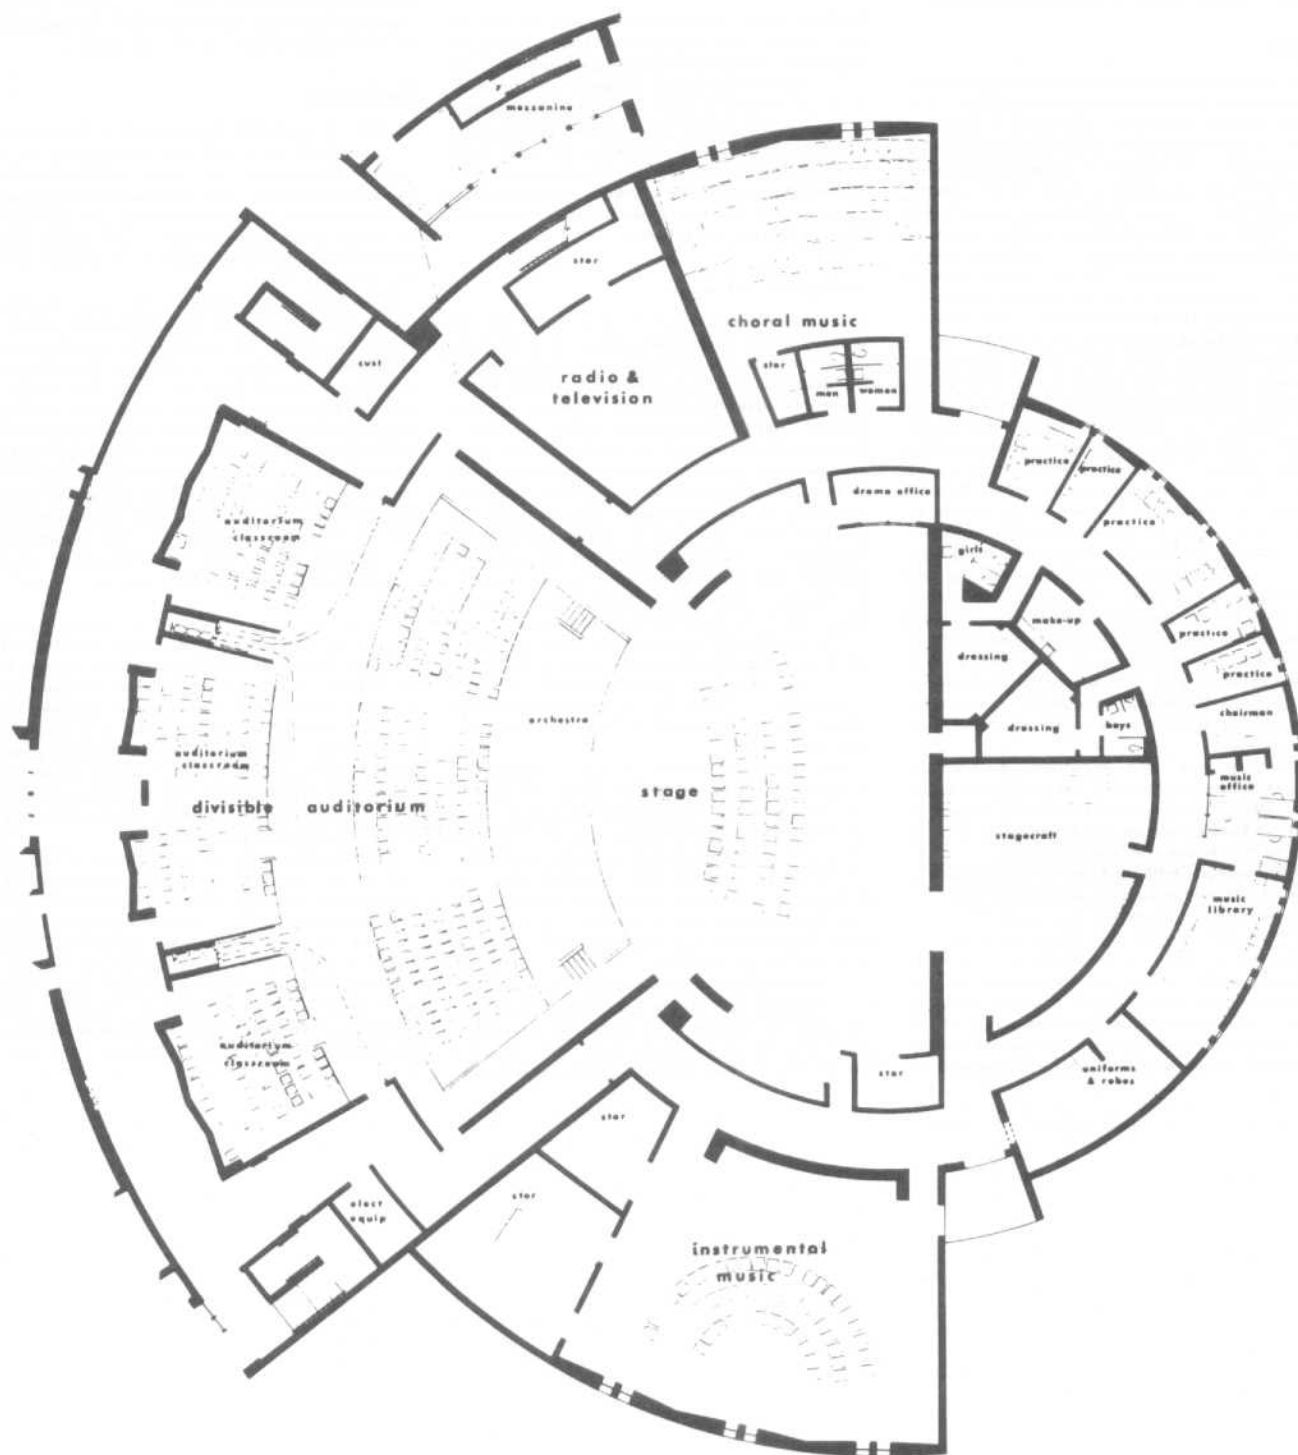

Fig. 6 Divisible auditoriums provide a means of increasing the use of large areas. Huron High School, Ann Arbor, Mich. Lane, Riebe, Weiland, Architects.

MUSIC FACILITIES

windows, in order to avoid light leaks. All doors should operate silently. Panic bars on exit doors are generally required by law but are sometimes rendered useless by padlocks and chains, an extremely dangerous practice.

Lights

There are many new concepts in stage lighting, whether the facility to be lighted is the proscenium theater, the open stage, or the modified proscenium stage. The border and footlight installations once popular in school auditoriums are no longer considered adequate. In addition to sufficient downlights for concerts and other nontheatrical presentations, school auditoriums need stage lighting for a number of specific dramatic purposes. The amount of lighting and the types required will of course depend on the design of the auditorium and the nature of the productions which are projected for it.

Front lighting from slots in the auditorium ceiling serviced by catwalks is highly desirable. Ellipsoidal spotlights are used to light the acting area. Additional spots may be desired in wall slots, and a follow spot operated from a booth in the rear of the auditorium is common. Spotlights (generally softer Fresnel types) are needed on battens or on stands or tormentor pipes to provide further illumination of the acting area. Borderlights and sometimes footlights are employed for toning and blending. Beamlights are used for back-lighting. Floodlights are used for background effects and special footlights are needed for a cyclorama. Sidelighting is sometimes provided by spotlights from a mobile tower in the wings. An elaborate college or community theater installation may wish to provide a light bridge.

Open stages and modified proscenium stages frequently provide for projected backgrounds. The lamp house for scenic projection may be located above the stage area or in a ceiling slot above the front curtain.

The stage switchboard may be located at the rear of the auditorium in a lighting booth; it may be located offstage on the stage floor, but out of the way of other operating equipment; or it may be located in an elevated position off the stage floor. They should be able to take care of an adequate number of floor pockets, three or four locations on both sides of the stage. These will vary in accordance with the size of the auditorium, stage, and its lighting equipment. A

dimmer system should be part of most school lighting installations.

Risers

Portable risers should be provided as part of the regular stage equipment. These risers, if adjustable to suit choral groups, orchestra, or band, make it possible to stage all kinds of musical activities even if the instrumental groups alone prefer to perform on the flat. Dramatic productions require a different type of riser and in addition to the standard construction, occasionally adjustable hydraulically controlled risers are used. Storage space for risers should be planned.

Orchestra Pits

Most school auditoriums need an adequate orchestra pit. The pit should be in direct proportion to the size of the stage and the size of the auditorium and above all, should be sufficient to house the potential orchestra of the school. That is, the potential school orchestra that would be required for performances of a musical play, operetta, or opera. The stage with a 45-ft proscenium would probably have an orchestra pit of sufficient size to seat 60 players, allowing 18 to 20 sq ft per player. Likewise, a stage with a 60-ft proscenium should have a pit large enough to accommodate a 100-piece orchestra. With a larger or small stage, the pit should be in direct proportion.

The pit should be deep enough so that the orchestra is completely out of sight of the audience. The director's podium should be high enough for him to be able to see the back area of the stage yet remain in full view of the orchestra.

The railing around the entire orchestra pit must be high enough to hide the orchestra yet low enough not to interfere with the sight lines of the audience. The head and the shoulders of the director may be visible over this orchestra pit railing. It is preferable, however, that the director be hidden from view of the audience so that there will be no distraction of any kind while the director is giving cues to the orchestra, cast, or performers.

A movable pit floor, usually known as a hydraulic pit, is a highly desirable though not inexpensive feature. The hydraulic pit floor should come up to stage level and then be lowered to the floor below. In this event the ac-

cess will be a simple matter through double doors and the problem of determining adequate pit levels for performance is immediately solved. The hydraulic pit floor will act as a good sound reflector when not being used as an orchestra pit. At that time the pit will probably be located slightly below the stage level.

Seating Area

A factor that is often overlooked in the design of an auditorium is the seating capacity. In a commercial theater and in certain other specific situations a hall is designed with the idea that it is necessary to have the entire potential attendance at one performance. The larger the attendance, the less expense involved, the more money made.

In an educational situation, however, the auditorium or theater is for an educational purpose, no matter at what level—elementary, secondary, or college—it is used. A fine program is prepared and, so far as the performance is concerned, there is value in having repeat performances. From this viewpoint it might be logical to reduce the seating capacity of the auditorium or theater and spend some of the limited funds in seeing that the auditorium has better equipment so that the performances can be presented adequately. This should be considered by school administrators and teachers when building the theater or auditorium.

There are other reasons for considering smaller seating capacity. Although audiovisual aids can be presented to large mass groups, it is difficult to hold the personal student-to-teacher relationship that can be attained in smaller groups. In addition to a projection booth at the rear, consideration should be given to a projector platform closer to the stage for use with short-range equipment. All booths and platforms should be located to clear the heads of people seated or standing.

The divisible auditorium is a concept finding increasing favor with those who need to justify the number of hours per day school facilities are used. Such auditoriums are designed to be divided by sound-retarding partitions into three or more areas for large-group instruction. Partitions may run from front to rear as well as across the auditorium. Provision for projecting films and other audiovisual materials should be planned for all areas. (See Fig. 6.)

BASIC SEATING DATA

Seating standards for use in theaters, auditoriums and similar buildings are developed on this and the following pages, which give tabular data and methods for laying out seating plans. Material is the result of research by Frederic Arden Pawley. Sources include seating manufacturers and architectural offices specializing in theaters.

Types of Seats

Construction and Finish Upholstery variations include *spring-edge* seats (most luxurious, more expensive); *box-spring* (nearly as comfortable);

spring-back; and *padded-back*. *Veneer-back* seating is suitable only for conditions subject to hard usage, as in schools. Acoustical control is more satisfactory with upholstered types.

Sizes Seats are designated by width, the depth front-to-back varying only slightly. Common sizes and recommended uses are shown below. In pew seating without individual arms, as in churches or arenas, a "sitting" is usually 18 in. wide.

Pitch of Back This will vary according to the vertical angle of vision to the center of interest. In general, greater pitches are used for front

portions of orchestra floors and more nearly vertical backs for elevated banks such as balconies.

Clearances In addition to those noted diagrammatically below, the following points should be considered: *Coves* at intersection of floor and walls (or risers) should be kept small (1½ in. radius) to permit close fitting and leveling of seat standards. *Balcony risers* cause cramped knee-room when 12 in. high unless back-to-back seat spacing is increased. End clearances in balconies should be increased to 2½ in. *Pitch of back* greater than average (see Fig. 7) also requires increased back-to-back spacing.

CLEARANCES

Fig. 7

SIDE ELEVATION

(End Standard shown Solid; Middle Standard Dotted)

SIZES AVAILABLE

W*	18"	19"	20"	21"	22"	23"	24"
D	26⅞	27¼	27⅝	28"	28⅝	28¾	29⅞

* 18" width not recommended; 19" width recommended only for ends of rows; 20" to 22" sizes for all locations

PITCHES: measured either by angle or horiz. projection (see diagram): 8¼" (usual max.); 7½", 6¾", (standard); 5¼" (usual min.) 4", 3" (special)

Scale ----- ¾" = 1'-0"

Note additional allowance of 1½" for each End Standard

PLAN—Several types of Ventilators are available. Preferred kinds are those occupying least space

TYPICAL SEATS

Types of Layouts

Rows These may be straight across entire theater, side banks may be canted, or entire rows may be curved. Advantages of each type are shown in Fig. 8. Min. radius for curved rows, due to seat construction, is 20 ft. Center for radii of rows and center of screen or stage need not coincide, although this is the ideal case. When rows are curved, a sloping auditorium floor should be a compound curve or amphitheater type to prevent tilted side seats.

Aisles These may be straight or curved, parallel or radial. Aisles should run at right angles to rows to eliminate "pockets."

Combinations of row and aisle types commonly used are shown in Fig. 8.

Continental Seating, most commonly used abroad, involves use of rows with unlimited number of seats. Local codes in this country often either prohibit its use or impose many restrictions. However, existing examples have proved safe and comfortable due to increased back-to-back seat spacing (up to 42 in.) which

is essential to scheme. Larger than usual side aisles or foyers and many side exits are required.

Code Requirements These govern (1) maximum number of seats in a bank, (2) aisle width, (3) crossovers (not uniform). Usual requirements are: (1) no seat more than seven seats from an aisle; (2) min. aisle width of 3 ft, increasing by varying factors in relation to length of aisles. (3) Requirements for crossovers, not uniformly subject to codes, vary. Consult local authorities.

MINIMUM SPACINGS FOR VARYING FLOOR CONDITIONS

Based on stock sizes with 5 1/4" pitch back

STRAIGHT ROWS

Uncomfortable for spectators at side, unequal stress on seats and backs

STRAIGHT, CANTED SIDE-BANKS

Same defects as straight rows though to less degree. Note that rows do not line up. Steps if required in aisles will be unsafe

CURVED ROWS

Recommended for comfort, ease of vision and safety

SIDE RAKE (Curved Rows)

Aisles cutting diagonally across rows produce dangerous "pockets" and waste space

Curved or straight radial aisles reduce number and size of "pockets"

DIRECTION OF AISLES

Fig. 8

AUDITORIUM DIMENSIONS

Preliminary estimates may be based upon the "Rule of Thumb" which is sufficiently accurate for rough sketches.

Tables. For such purposes as financing, working drawings, etc., follow method outlined in Examples A, B, C and D. Variations between the two methods are to be expected.

EXAMPLE A: Given auditorium area = 87'-0" x 56'-5" or 4900 + sq. ft., how many 20" seats, 36" back-to-back?

1. Rows: In Table I, 36" col., at 87'-0" depth, No. rows = 29
less cross-overs (1 row at front, 4 at rear) = 5
Rows available for seats = 24
2. Aisles: Table II, increase in aisle width per row = 0.75"; 0.75 x 24 = 1'-6"
Total increase = 1'-6"
Min. aisle = 3'-0"
Max. aisle = 4'-6"
3. Seating Scheme: Select tentative scheme; 2 aisles, 2 dead-end seat banks, 1 center bank. From typical code, dead-end rows may be 7 seats long, center rows 14 seats. In Table IV 14-20" seats = 23'-7"
7-20" seats = 11'-11"
7-20" seats = 11'-11"
From (2) above, 2 aisles = 9'-0"
Total width = 56'-5"
Seats per row = 28
4. Total No. of Seats: (Table III) = 672
or 28 x 24 = 672 seats

EXAMPLE B: Given capacity of 672 seats, what are auditorium dimensions?

This problem is the converse of "A".

EXAMPLE C: What is radius of any row?

To radius of back of first-row seats add desired value from Table I.

EXAMPLE D: How many and what sizes of seats can be used in rows shortened by curved or radial aisles? See Table IV.

RULE of THUMB for SEATING AREA:

Allow 7½ sq. ft per Seat, including Aisles and Cross-overs.

This is sufficiently accurate for preliminary planning.

Table I - Depth Dimensions (Ft.-In.) for Various Spacings

No. Rows	Overall Depth for Seat Spacing (Back-to-back) of:										
	32"	33"	34"	35"	36"	37"	38"	39"	40"	41"	42"
1	2-8	2-9	2-10	2-11	3-0	3-1	3-2	3-3	3-4	3-5	3-6

End Allowances: Normal 3" allowance to accommodate 2 end standards per row is included above. For balconies with steps in aisles allow 2" additional.

Seat Sizes: Common sizes shown. Seats are also available 18", 23" & 24" wide. 18" size not recommended. Limit use of 19" seats to ends of rows for comfort.

Choice of Seats: Note that for longer rows two choices of seat sizes are available. Example: Row length = 14'-9"; six 19" seats and three 20" may be used; or, two 21" and six 22". Dotted lines separate choices. Dimensions not fitted by stock sizes are omitted.

By AUGUST HOENACK, Chief, Architectural and Engineering Branch, Division of Hospital and Medical Facilities, Public Health Service, U.S. Department of Health, Education and Welfare

INTRODUCTION AND FLOW CHARTS

The hospital as a building type is composed of complex components, each of which could well tax the talents of architects, mechanical engineers, and the other professions and skills involved in their design and construction. Material relating to all these components would fill a book. Therefore, the following have been selected for discussion in this section:

- Bedrooms
- Nursing units
- Surgical suite
- Nursery
- Pediatric unit
- Diagnostic x-ray suite
- Teletherapy unit
- Cobalt-60
- Electroencephalographic suite
- Physical therapy department
- Occupational therapy department
- General hospital laboratory
- Labor-delivery suite
- Radioisotope facility

The material presented here has been selected, not necessarily as a guide from a functional standpoint or to indicate what the hospital may need, but rather as examples of critical space organization involving specialized equipment and facilities which are peculiar to a hospital. The extent of services, kind of equipment, space requirements, etc., will vary with each hospital and must be related to the services the hospital is to perform. Consequently, the information presented here must, of course, be adapted in each case.

Much has been written on the subject of the design and construction of hospitals. An adequate bibliography of this material is beyond the scope of this section. The architect who is not acquainted with hospital design should obtain additional information and bibliographies from such sources as the Bacon Library of the American Hospital Association in Chicago and the U.S. Public Health Service in Washington, D.C.

Figure 1 shows generalized flow charts for the hospital as a whole and for various departments which are not discussed in the following pages.

Bedrooms*

It was not the committee's purpose to include an analysis of the number of beds per nursing unit, or the proportions of single, double and four-bed rooms within given units. This study is limited to the individual room *per se*, to a review of numerous small but often vital details that make either a good room or an unsatisfactory one. These details are fine points that an administrator or architect should be familiar with before departing to something more original, if that should be his wish.

In general, the many room plans reviewed

have basic similarities but many variations in detail. Accompanying plans have been specially drawn to illustrate the majority of features that will be discussed. It must not be construed that these represent ideal or minimum standards. (See Figs. 2 to 6.)

Size

First point of interest is the considerable variation in room sizes. Ranges of net clear floor area from corridor door to window stool, not including built-in wardrobes, are:

Single rooms: 117 to 172 sq ft (deluxe are larger)

Double rooms: 157 to 210 sq ft

Four-bed rooms: 308 to 401 sq ft

Major differences are found in depth of rooms from inside of exterior wall to room side of corridor partition, all the way from 14 ft-6 in. for single rooms or 15 ft-0 in. for double and four-bed rooms to 21 ft-8 in. for all types. These differences are caused principally by varied space requirements of one or two beds in combination with various plumbing facilities—they reflect the endless search for a common denominator which will have flexibility to accommodate several combinations of room and toilet requirements within a uniform building dimension and fenestration without waste of expensive space.

In the two and four-bed rooms a clear distance of 14 ft-0 in. for two beds and two bedside tables is "snug," but it should be noted that the majority of rooms studied measure nearer to 15 ft-0 in. clear, which is the USPHS standard. Lavatory, toilet door, or wardrobe door do not encroach into these clear dimensions in the better rooms.

In the other dimension, comments of administrators evoke no complaints about single rooms as narrow as 10 ft-0 in. to centers of partitions—rooms up to 12 ft-0 in. on centers draw comments from "excellent" to "more than ample." Majority of double bedrooms are 12 ft-0 in. on centers and are well regarded—smaller ones are criticized for being too tight. Four-bed rooms range from acceptable minimum of 20 ft-0 in. on centers to more than 24 ft-0 in.

Closets

In almost every case individual hanging space is provided for each patient, often in the form of built-in metal wardrobes—sometimes these are in combination with dressers, with mirrors over. One caution was offered that mirrors should not be so placed as to reflect light into patient's eyes.

Furniture

There is uniformity in every plan reviewed in the way beds are set parallel to exterior wall, so that patients can look out window without facing directly into the bright sky. Motor-operated high-low beds are also uniformly popular—it should be noted that they may be a full 7 ft-3 in. in overall length.

There is no uniformity in position of bedside table. It may be placed on near side of bed as

one enters room, or on far side, or sometimes on patient's right or left, whichever way the bed faces. No preponderant preference can be detected. The typical bedside table measures about 16 in. x 20 in.

Plans reviewed did not concern themselves with other furniture. In single rooms, especially, the presence of a bureau, side chair, arm chair, ottoman, or television set is partly dependent on economic status of patient being served. These items take space and deserve attention in the planning stage—they may well affect overall room size.

Plumbing Fixtures

Next to room size the most important architectural problem is disposition of plumbing facilities. Although minimum budget hospitals are still being built without a toilet connecting to every bedroom, a private toilet is now regarded as a basic feature with each bedroom. It is perhaps axiomatic that in almost every case a bedpan cleansing device is incorporated. 2 ft-10 in. to 3 ft-2 in. by 3 ft-10 in. to 4 ft-10 in. are the dimensions noted for individual toilet rooms, usually with grab-bars on one or both side walls. Locating water closet slightly off-center in the room allows a little more space on wider side for manipulating cleanser—the latter needs only cold water and is usually on the right as you face back wall. Some plans indicate bedpan rack or cabinet within toilet room—otherwise bedpan is stored in bedside table.

Several plans were reviewed which showed shared toilets between two single or double rooms. While this arrangement may save some space and expense, it presents its own problems such as added disturbance to patients, special door hardware, and lack of flexibility in room assignment to patients of opposite sex. It is interesting that the administrators with this type of accommodation offered no comment on these points. The committee infers that the shared toilet is valid only in large hospitals, in which separation of sexes is a lesser problem.

Location of lavatory reveals about an even choice between placing it in bedroom proper, where it invites more frequent use by attending nurses and physicians, or in toilet rooms, where it is less institutional-looking to patient and visitors. It is known that some thoughtful hospitals purposely set lavatories at 3 ft-0 in. above floor—in other plans studied, the lower, conventional residential height is observed.

Not many toilet rooms have tubs, which make them complete bathrooms off bedrooms. This choice is undoubtedly a matter of economics of the particular hospital. The fact that almost no shower stalls appear leads the committee to conjecture that most hospitals are content to have shower heads in tubs, relying on suction-cup rubber mats and strong grab bars to avoid injury to patients from slipping.

Doors and Windows

Standard bedroom door width is 3 ft-10 in. or 4 ft-0 in. This can be reduced by 2 in. with offset hinges. A slight majority of doors to single

Fig. 5. Double room, medium size

Fig. 6. Single room, medium size

and double rooms are hinged on side toward beds, so that door ajar serves as screen to patient. Toilet room door widths are 2 ft-0 in. to 2 ft-4 in. swinging out into bedroom, except where surface-bolted or pivoted hinges are used, so that doors can be removed in the event a patient in toilet room faints and falls against door.

The wide variety of window treatment suggests that climate, orientation, esthetics, economics and other considerations do more to govern this architectural feature than any predetermined optimum standard. It is interesting that administrators' comments in this general area say little about psychological or therapeutic values of wide vs narrow or high vs low windows, but do offer practical complaints about windows that are drafty or difficult to clean and wood stools that spot too easily. Preferences are expressed for marble and laminated plastic stools. A definite division of opinion is found between those who prefer nothing but drapes and those who favor only Venetian blinds at windows. The committee notes that low window stools offer patient an opportunity to see out when his motorized bed is in its low position.

Room Finishes

There is no strong preference for one type of flooring material over another. Inquiries made about oversize sloping bases to keep furniture away from walls reveal that those few who have them seem satisfied, whereas only one administrator without them expressed a wish that he might have had them. Wall behind bed is the only location within a bedroom where a sloping base appears to have merit. Plaster walls are most common. Acoustical ceilings are not considered essential, even in multi-bed rooms—use of a suspended acoustical system is more valuable for access to mechanical work than for its acoustical properties.

Built-in Equipment

Built-in wardrobe-dresser-recessed-mirror combinations have been discussed above. Some emphasis is also found for separate 9 in. wide flower shelves bracketed on wall beside or opposite bed, about 4 ft-6 in. above floor. There are a variety of cubicle curtain arrangements in multi-bed rooms, from the simplest cross-room tracks to complete enclosures around each bed.

Lighting

A study of the rooms shows that no single, a few double, and most four-bed rooms have ceiling fixtures for general illumination. In almost all rooms there is a wall fixture over head of bed, mounted from 5 ft-2 in. to 6 ft-6 in. above floor. There are numerous fixtures on the market today for this purpose, providing varying combinations of direct and indirect light. The one prevailing comment of a number of administrators is that no wall light gives adequate illumination for examining the patient. Another caution is to control light in multi-bed rooms so that it will not shine in another patient's eyes—this frequently happens across the room in four-bed rooms. Almost all rooms have night-lights, either set in wall at a low elevation or incorporated in over-bed light. The one prevailing comment here recommends switching the night-light out in corridor or near room door, rather than at bedside. (See Fig. 7.)

A special wrinkle for single rooms, where private duty nurses may be in attendance, is a ceiling down-light over a chair near door into the room, at which location the nurse can guard patient from unwanted visitors and at same time read comfortably day or night without bothering patient.

Other Electrical Work

The audio-visual nurse's call is almost universally used and gets a popular rating among administrators who commented—except for use in pediatrics. In some cases the speaker is located in ceiling over bed. In one instance a request is made for the pilot light also in ceiling, as being more easily seen by patient. On walls with two beds the use of one call for two beds or provision of separate calls is about an even choice.

In a small percentage of hospitals several radio channels are piped in at head of bed. In fewer instances the same is true of TV; most TV sets are portable and provided through a rental agency.

Oxygen and Suction

Oxygen is piped in from a central source in most rooms studied. Outlets are 4 ft-0 in. to 5 ft-6 in. above floors—5 ft-0 in. minimum is the NPFA Bulletin 565 standard if outlet is not recessed. There is an even division of opinion concerning location of oxygen outlets,

Fig. 15 Detail of nursing station and utility unit

HOSPITALS

Surgical Suite

either on near side of bed, as one enters room, or on far side. Suction is provided in all rooms in approximately one-third of the hospitals, in some rooms in one-third, and in no rooms in one-third. Outlets are either grouped in same plate with oxygen or they are separate, beside or below oxygen. Piped compressed air in bedrooms is noted only occasionally.

Air Conditioning

The incidence of airconditioning is still something that depends on climate and economics. Individual room units present no problems of cross-contamination of air from one room to another. Central systems do create problems if recirculation is desired. A check across the country indicates that opinion is divided on extent to which central recirculation should be permitted.

Organization of Wall Outlets

An overall glance at the numerous room layouts studied by the committee emphasizes the clutter of wall outlets and paraphernalia of many kinds at head of each bed. In general they detract from appearance of room. A checklist for a well-equipped bed in a single room will include some 24 different facilities! In order to minimize the scatter effect at normal eye level, the committee suggests that half of these facilities could be consolidated in a low-wall outlet through a single flexible cable to bedside table, where many items would be within reach of patient. Only two items might then occur on wall at eye-level—oxygen outlet (code requirement) and over-bed light (if used). Following check-list gives an indication of the thinking of some of the committee on this point:

Portable Bedside Panel (Patient's Control)

- Nurses' call switch, pilot light, monitor light
- General room illumination switch, dimmer control
- Reading light switch
- Room thermostat remote control
- Electric blanket control
- Electric clock
- Duplex convenience receptacle
- Radio station selector (central radio system)
- Jack for pillow speaker (ceiling speaker in private rooms)
- Provision for TV remote control to be clipped onto panel
- Provision for telephone instrument (bracket type)

NURSING UNITS

Integral with bed

- Bed control (within patient's reach, but with nurse-controlled cut-off feature)

Ceiling

- Nurses' call micro-speaker
- Radio speaker (private rooms only)

High on Wall (60 in. or higher)

- Over-bed light fixture (direct and indirect)
- Oxygen outlet

Low on Wall (approximately 24 in.)

- Receptacle for portable bedside panel
- Night light (switched from corridor)
- Telephone jack
- Double duplex receptacle (bed, oxygen tent, portable x-ray, heating pad, etc)
- Remote recording instrument receptacles (temp, pulse, respiratory)
- Suction outlet
- Bracket for suction bottle

Double Corridor Nursing Floor

Figure 14 shows a typical double-corridor nursing unit which is often utilized in hospital planning. It has the following advantages:

1. It permits a closer relationship between the patient bedrooms and the nursing station and other service areas.
2. It permits greater flexibility in segregation of patients for various medical reasons.
3. Much of the staff activity and particularly conversation can be carried on within the service unit complex, thus cutting down noise in the patient corridor.

Figure 15 indicates more clearly the nursing station and utility room arrangement. The clean utility is designed to accommodate carts for storing linens, utensils, and other supplies, which would be brought from a central supply and sterilizing unit. Elevators are located outside the nursing unit to cut down on the amount of noise. This would also permit a future nursing unit to be located on the other side of the elevators.

The success of this plan depends, to a great extent, on well-designed air conditioning and lighting, particularly for the center unit. While this nursing floor consists of two 25-bed nursing units, many authorities believe that greater efficiencies are obtained in having a larger ratio of beds per nursing station. This particular nursing floor might easily be extended one or two bays, increasing the capacity to 62 or 70 beds.

This plan also demonstrates how an intensive nursing service can be integrated into the same module or bay which accommodates the typical patient room. One 6-bed intensive ward is shown, and the adjacent typical double rooms can accommodate intensive-care patients when the need arises.

SURGICAL SUITE

The surgical suite of the general hospital is a very complex workshop. It is one of the most important departments of any hospital, and its planning is complicated by the diversities of opinion and experience of the many persons involved in policy decisions essential to development of a good program of requirements.

We say a "program of requirements" rather than "plan." Before any intelligent planning can be done by the architect, there must be a meeting of minds on the size of department; i.e., the number and type of operating rooms and the work methods to be followed in the supportive areas. Administrators, surgeons, anesthetists, surgical nurses, all must participate in the preplanning analysis of needs and functional methods. The architect must have a wide understanding of various management procedures to be sure that all are discussed in reaching any conclusions with the particular group involved.

The number and type of operating rooms is the first major decision. In the general hospital, the tendency is to have all major operating rooms as nearly identical as possible to facilitate scheduling of various surgical procedures. Free floor space should be 18 ft by 20 ft, or approximately 350 sq ft. Many surgeons and surgical supervisors recommend 20 ft by 20 ft free floor space.

The planning and equipping of each operat-

ing room are based on a series of questions, such as: (a) size, (b) usage, (c) environmental control*, (d) lighting—surgical and general illumination*, (e) intercommunications and signal systems*, (f) electronic equipment and monitoring system*, (g) service lines, such as suction, oxygen, nitrous oxide, compressed air, (h) provision for x-ray, not only x-ray tube stand but control, transformer, and necessary lead protection, (i) provision for TV camera, movie cameras, other recording equipment, (j) safety precaution in hazardous areas, (k) cabinet work, supply cabinets and storage for operating table appliances, (l) need for clocks, film illuminators.

The rapid development of cardiac and neurosurgery is creating a demand for one or more extra-large operating rooms. This type of surgery calls for a larger team of surgeons, nurses and technicians, plus a great deal of extra equipment, such as heart-lung machines, hypothermia equipment, etc.; also electronic devices for measuring bodily functions, i.e., electrocardiograph, electroencephalograph, blood pressure, respiration, body temperature, etc. Today many architects are providing an "instrumentation" room adjacent to or between two extra-large operating rooms to accommodate such equipment, which is frequently not explosion-proof. The floor of any such room is usually elevated approximately 3 ft above the operating room floor. Plate glass panels permit vision into operating rooms, and through-wall conduits accommodate wires and other leads of various appliances in the instrumentation room to the surgical field. Such an area can also house the TV control and monitor (if used), x-ray controls, etc.

In the hospital as a whole, the actual patient area is only a very small per cent of the total. The same is true within the surgical suite. The operating rooms themselves will account for only about one-fourth of the total area required for the suite with its supportive functions such as—

Offices and administration areas, scrub areas, work and supply rooms, laboratory, dark room, post-anesthesia recovery, holding or induction areas, lounge, locker and toilet rooms for various personnel groups, conference or teaching rooms, and circulation within the department.

The analysis of various suites illustrating this article show a spread from 1115 sq ft to 1585 sq ft total gross area per operating or cystoscopic room (if included)—and every suite could use more gross floor area for storage, according to comments. Thus, a suite of eight operating rooms averaging 350 sq ft each = 2800 sq ft \times 4 = 11,200 sq ft estimated total area required—or 1400 sq ft per operating room.

Within the surgical suite we have three basic zones predicated on three types of activity and circulation involved, and the degree of sterility to be maintained. The preplanning analysis of these areas is just as important as the determination of the number and type of operating rooms.

Outer zone: Administrative elements and basic control where personnel enter the department, patients are received and held or sent to proper holding areas of inner zone; conference, classroom areas, locker spaces, any outpatient reception, etc.

Intermediate zone: Predominantly work and storage areas; outside personnel will deliver to this area but should not penetrate the inner zone. The recovery suite, if completely inte-

*These subjects have so many ramifications they are only mentioned here.

HOSPITALS

Surgical Suite

grated with the surgical suite, is an intermediate or outer zone activity.

Inner zone: The actual operating rooms, the scrub areas, the patient holding or induction areas. All alien traffic should be eliminated. Here we want to maintain the highest level of cleanliness and aseptic conditions.

Outer zone administrative areas have increased in importance. Offices are needed for the surgical supervisor, the clerks who manage scheduling and paper work, the clinical instructor (particularly if there is a school of nursing), possibly the chief of staff. There must be provision for surgeons to dictate medical records.

And don't forget the patient. After all, he is the primary concern. Who is responsible for his transportation to the surgical suite, and on whose bed or stretcher? How is he checked in and where does he wait if the room for which he is scheduled is not ready? Who has not seen surgical corridors lined with occupied stretchers for want of adequate holding, preparation or induction areas? Another factor is added if any ambulant outpatient work is to be done. There must be provision for receiving, controlled waiting, dressing rooms and toilets.

A variety of persons must be provided with lounge, locker and toilet space—surgeons (male and female), nurses, technicians, aides, orderlies. Coffee and cola seem to lubricate the entire department; some systematic provision for their supply is warranted.

A conference or classroom for departmental meetings and in-service training programs is easily justified.

The access to all these areas should be removed from strictly surgical areas, as people are entering and leaving in street clothes and should not penetrate into other zones until after changing shoes and clothing.

The planning and equipping of the intermediate zone are based on the method of processing and storing of the thousands of items involved. It is fairly common practice for the central sterile supply department, elsewhere in the hospital, to be responsible for the pre-

paration and autoclaving of all surgical linen packs, gloves, syringes, needles, and external fluids. The storage of these items to be used in surgery becomes the responsibility of the surgical department and adequate space must be provided for a predetermined level of inventory. (See Fig. 1.)

The method of processing surgical instruments has been the subject of various research projects, notably at the University of Pittsburgh (see *The Modern Hospital*, November 1955). The new ultrasonic cleaning equipment is eliminating a time-consuming, laborious process. The cost of the equipment discourages duplication and encourages the consolidation of work areas where lay personnel can be trained under close supervision to carry out approved processing techniques.

The method of packing and sterilizing instruments and utensils will determine the size, type, and location of autoclaves needed. Consideration must be given to inclusion of an ethylene oxide sterilizer for cystoscopes, bronchoscopes and delicate surgical instruments which cannot be sterilized by steam or high temperatures. How and where instruments will be stored is another decision to be made.

Suitable storage space must be provided for: (a) clean surgical supplies such as extra linen, tape, bandage materials, etc.; (b) parenteral solutions, external fluids or sterile water; (c) essential drugs and narcotics; (d) blood supplies, bone bank, tissue bank, eye bank, etc.; (e) radium and isotopes used in surgery.

It seems impossible to provide adequate centralized garage-type spaces for bulky equipment not in constant use. Dr. Carl Walter has estimated that an average of 80 sq ft per operating room is needed.

The intermediate zone also houses the facilities for handling waste, soiled linen, etc., and janitorial equipment for routine housekeeping.

The anesthesia service cannot be short-changed. It may spread over all zones of the surgical suite. Office space is required, work and storage space for equipment. And most im-

portant is the decision on where induction of the patient is to take place: centrally to all rooms, locally in induction areas (sometimes referred to as preparation or holding rooms) or in the operating room proper. There are acknowledged hazards in moving anesthetized patients and equipment. Induction areas should permit quicker turnover in operating room usage, but they also require more anesthetists and nurses to administer.*

The post-anesthesia recovery room has become an integral part of the surgical suite in most cases. The size will vary from one-and-a-half to two beds per operating room. There is a close relationship between the anesthesia department and the recovery room.

Any frozen section laboratory should be located near the entrance of the surgical suite so that laboratory personnel need not penetrate the inner zone.

Any dark room facilities should be located to serve those rooms generating greatest load of film, normally the cystoscopic, urological and orthopedic services. It should be accessible from a corridor to prevent alien traffic through any operating room.

Inner zone planning includes the operating rooms and their essential supportive elements. Decisions must be made on the type of scrub-up sinks or troughs and their location providing minimum travel to the operating room to eliminate chance of contamination after scrub procedure.

The need for local "substerilizing" rooms is being questioned by many authorities. The trend toward centralization of work areas and sterilizing equipment, and the changing techniques of instrument packaging are reducing the importance of the substerilizing area. Circulation travel distance and work patterns are factors determining the need for decentralized work areas. When such areas are provided there should be staff access for servicing and stocking them without going through an operating room.

The program of need dictates the gross area required for the surgical suite. Recent developments indicate that more efficient departments with minimum travel distances can be planned in bulky squarish areas. This tendency has affected the location of the surgical suite in relationship to the hospital as a whole. The suite has come downstairs to a lower floor where it is more possible to spread out and achieve the desired shape, divorced from the usually narrow structural pattern of a nursing unit. Planning within the squarish areas has been made possible with the parallel development of air conditioning and artificial lighting. Dependence upon windows for ventilation and light is a thing of the past. The optimum conditions of temperature, humidity, and light level can be controlled by mechanical means far better than by nature. (See Fig. 2.)

The surgical suite location must mesh with the total circulation pattern so that patients can be moved to and from surgery with a minimum of travel through other hospital services. Its location is also affected by its close relationship to three other major hospital services—the x-ray department, the clinical laboratories, and the central sterile supply.

One other important factor in the location of the surgical suite is future expansion. Anticipate ways and means to permit growth in an orderly fashion without upsetting the basic relationship of internal organization—or without extending lines of travel to unacceptable or uneconomical lengths.

*Experience with various suites indicates that what was planned for induction frequently is converted to other causes.

Fig. 2 Typical plans of operating suites

NURSERY*

As one of the areas in the hospital where patients are most vulnerable to infection, the nursery should be planned to provide the best means for the care, safety, and welfare of the infants. Although the plans and diagrams, shown here, have been developed for hospitals of specified sizes, the principles set forth apply to all hospitals, large or small, new or old.

Basic recommendations for planning nurseries that have been developed, based on clinical experience and study, include: limiting the number of infants in each nursery; wide spacing of bassinets within each nursery; separation of bassinets by cubicle partitions; promoting the use of aseptic techniques and individual care by providing, among other things, ample space and handwashing facilities; limiting the number of bassinets served by one nurses' station; separating facilities for premature infants and for observing infants suspected of having infectious conditions;

* The study from which this article was condensed was prepared for the Division of Hospital and Medical Facilities, Public Health Service, and the Children's Bureau, Social Security Administration, by O. Bernard Ives, architect. Copies of the study may be obtained from Superintendent of Documents, U.S. Government Printing Office, Washington.

NURSERY FOR 440 LIVE BIRTHS PER YEAR IN HOSPITAL OF APPROXIMATELY 50 BEDS.

The number of bassinets and maternity beds required is based on number of live births expected in hospital per year, rather than a rule-of-thumb relationship to the over-all bed complement. Six to 8 per cent (up to 12 per cent in poor economic areas) of the total live births will be premature (low birth weight of 5 pounds 8 ounces)

Fig. 1 Plans for nursery in 50-bed hospital.

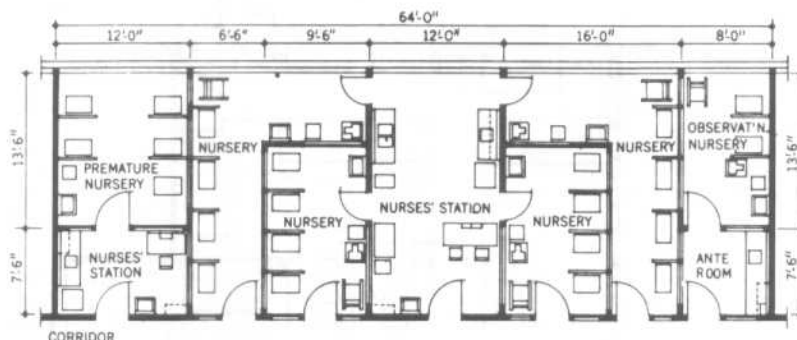

HOSPITALS

Nursery

NURSERY FOR 880 LIVE BIRTHS PER YEAR IN HOSPITAL OF APPROXIMATELY 100 BEDS. The estimated number of premature births divided by 18 (number of 20-day average stay periods in a year) will equal the average number of premature bassinets or incubators required. This figure must be adjusted for 100 per cent occupancy (often assumed at 70 per cent). A premature center nearby would eliminate need for such facilities in the hospital.

COHORT SYSTEM NURSERY FOR 880 LIVE BIRTHS PER YEAR IN HOSPITAL OF APPROXIMATELY 100 BEDS. In hospitals using the cohort system, babies born within 48 hours of each other are kept in the same nursery, arriving and leaving together, in theory reducing cross-infection through the elimination of over-lapping of babies with infections. Cohort nurseries are thoroughly cleaned and disinfected between discharge of one cohort and admission of the next

NURSERY FOR 1,500 LIVE BIRTHS PER YEAR IN HOSPITAL OF APPROXIMATELY 200 BEDS. Size of full-term portion of this nursery, as well as the others shown, is based on estimated number of live births per year less the premature births. This figure is then divided by 73 (the number of five-day average stay periods in a year) and adjusted from this 70 per cent occupancy total to a 100 per cent occupancy figure. Observation bassinets are provided at rate of 10 per cent of full-term bassinets, in nurseries with capacity of 20 or more. In smaller nurseries a minimum of two observation bassinets are provided

Fig. 2 Plans for nurseries in 100- or 200-bed hospitals.

DETAIL PLAN, TWO EIGHT-BASSINET FULL-TERM NURSERIES AND NURSES' STATION. Typical arrangement of a pair of full-term nurseries with nurses' station between allowing two nurses to tend 16 bassinets (or a maximum of 20) from one position. Recommended items of furnishings and equipment are shown located in what is considered their proper relationship to each other and to the complete nursery-nurses' station layout

DETAIL PLAN, TWO PAIRS FOUR-BASSINET COHORT SYSTEM NURSERIES AND NURSES' STATION. A cohort system arrangement similar to the layout above, and of the same size. As in the conventional plan (above), the four cohort nurseries may be tended by two nurses working together from a single centrally-located nurses' station. Workspace required will be approximately the same in both types

LEFT: DETAIL PLAN, FIVE-INCUBATOR NURSERY WITH NURSES' STATION. MIDDLE AND RIGHT: MAXIMUM (THREE-BASSINET) AND MINIMUM (TWO-BASSINET) OBSERVATION NURSERIES. The minimum and maximum size observation nurseries have anterooms between nurseries and corridors, provided with approximately the same facilities as work and treatment areas of full-term nurseries

28. Door with upper panel of clear glass

Fig. 3 Detail plans for three types of nurseries.

HOSPITALS

Nursery

and providing optimum conditions of temperature, relative humidity and ventilation. Figures 1 to 13 show a variety of nursery plans.

Full-term nurseries should be located in the maternity nursing unit as close to the mothers as possible and away from the line of traffic of other than maternity services. An area of 30 feet per infant is recommended, exclusive of the nurses' station.

The extent of the spread of infection in a nursery can be reduced as the number of infants in each nursery room is reduced. The optimum number of full-term infants that can be cared for by a member of the nursing staff is in the range of 8 to 10.

Bassinets should be at least 2 feet apart and, if partitions are used, cubicles should be large enough to permit bedside care. Partitions should be glazed or transparent so that the infants can be easily observed by the nurse. To facilitate cleaning, partitions should not extend to the floor. Cubicle partitions might extend only from the bottom of the bassinet to 24 inches above. The supporting frames of the partitions may be attached to the ceiling and wall. Where a wall is not available, as in an island arrangement, some supports must extend to the floor.

In nurseries without cubicle partitions bassinets are often crowded together side by side. Although cubicle partitions may be objectionable from the standpoint of cleaning (and are often unsightly), they help to ensure that bassinets are properly spaced.

Fixed-view windows between the nursery and the corridor permit visitors to view the infants from the corridor. These windows must be wire glass set in steel frames and must conform to National Fire Code requirements. Fixed view windows in partitions between nurseries and the nurses' station or between two nurseries facilitate observation of all infants in the area. These windows may be of clear plate glass or lucite and should be as large as practicable.

A door direct from each nursery to the corridor is recommended to permit faster evacuation in case of fire and easier movement of bassinets from the nursery to the mothers at feeding time and to avoid traffic through the nurses' station. This door, hung in a steel frame, should have a wire glass panel and must conform to National Fire Code requirements.

Furnishings and equipment for each full-term nursery should include, in addition to the items shown in the plans, a suction bulb or a mechanical device with a soft rubber tip and individual catheters for individual infants for each full-term (and premature) nursery. Controls of the suction device should include a regulator to limit the suction to avoid injury to the infant. Suction should be provided from a central system.

A four-bassinet nursery lends itself well to the "cohort" system, in which babies born during the same interval (no more than 48 hours) are kept in the same nursery. Babies arrive and leave together. After the departure of each cohort, the nursery is thoroughly cleaned and disinfected before admission of the next cohort, thereby—in theory—breaking the chain of possible cross-infection by eliminating the overlapping of babies with infections.

The use of four-bassinet nurseries does not imply increased staff. Two four-bassinet nurseries may be under the care of one nursing

person if she wears a scrub gown and scrubs properly between visits to each nursery. Two such nurseries may be considered the equivalent of one eight-bassinet nursery in assigning nurses' station and work space. Furnishings and equipment will be the same as those for full-term nurseries.

Since premature infants require more specialized care than full-term infants, a reasonable ratio of staff to premature infants is set at one to five. Thus, a premature nursery room should accommodate no more than five infants and should have a minimum area of 30 square feet per infant. A separate nursery is usually not indicated if less than five infants are to be cared for at one time. In such cases, space for them can often be provided in the full-term nursery. One nurses' station may serve two premature nurseries, or a premature nursery and a full-term nursery if the nurseries are paired.

In a premature nursery where suitable environmental temperature and humidity are maintained, only 50 to 75 per cent of the premature infants may require incubators. Furnishings for premature nurseries will be similar to those in full-term nurseries, aside from the incubators.

An observation nursery should be provided for infants suspected of infection. When positive diagnosis is made, the infant is transferred elsewhere in the hospital and placed on isolation precautions. However, if diagnosis is not positive the infant may be returned to the regular nursery provided he has not been exposed to an infected infant in the observation nursery.

The observation nursery should be a completely separate unit, but it should be located adjacent to a full-term nursery with a glazed partition between to permit observation by the nursery staff. A minimum of 40 square feet per bassinet is recommended to provide adequate space for bedside care and treatment of the infant.

Observation bassinets should be provided at the rate of 10 per cent of the full-term bassinets. A minimum of two—and a maximum of three—bassinets are recommended for each observation nursery. These nurseries may be repeated as many times as necessary to provide the required complement of observation bassinets. Furnishings and equipment will be similar to those in full-term nurseries.

An anteroom should be provided between the nursery and the corridor. This area should contain the same facilities as the work and treatment areas for full-term nurseries.

The nurses' station serves as a control point and also provides workspace for the nurse and an area for treating infants. The nurse's desk should be placed so that the entrances from the corridor and from the station to the nurseries can be supervised. The nurseries should be visible through observation windows in the partitions.

A station between two nurseries will require a double desk for two nurses. No more than two full-term nurseries, each housing 8 to 10 bassinets, should be served by one nurses' station. In the cohort system, four nurseries, of four bassinets each, may be so served.

The nurse's workspace should occupy a separate area at one end of the nurses' station. This arrangement affords the nurse full view of the infants while attending to most activities. The treatment area should be located near the entrance to the nurses' station so the physician need not walk through the workspace. Routine

examinations and treatments should be carried out at the bassinets in the nursery. A physicians' scrub area should be located at the entrance of the nurses' station. The description of the full-term nurses' station also applies to premature nurseries, except that the treatment table is omitted. Other necessary areas, not shown in the plans, include formula rooms, nurses' locker rooms, demonstration rooms and storage.

Air conditioning will be required for nurseries to ensure the constant temperature and humidity conditions so beneficial to care of the newborn. In addition, the air-conditioning system, through the ventilating features, will remove odor and will materially reduce the bacterial contamination of the environment.

PEDIATRIC NURSING UNITS*

The floor plans of pediatric nursing units shown in Figs. 1 and 2 illustrate suggested arrangements of the patient rooms and the supporting facilities described in the text. These plans are designed also to conform with other nursing units of the hospital.

The total bed count in each plan exceeds the recommended maximum of 20 beds per nursing unit because provision has been made for parents to sleep in. The number of sleep-in beds will vary with hospital policy and with the number of parents who are able or who wish to sleep in. All bedrooms are sized and equipped to accommodate full-size hospital beds as well as smaller youth beds and cribs.

Another feature is the extensive use of glass in partitions between rooms and in corridor partitions. This provides the visual control most necessary in pediatric nursing.

Rooms for sick infants and isolation rooms are located for direct observation from the nurses' station. The nurses' station is centered in each unit, thus reducing travel distances and allowing general observation of activity and traffic.

Workrooms are centrally located in the single pediatric nursing unit (Fig. 1) and conveniently accessible to both nursing units as shown in Fig. 2.

An important therapeutic area is the dayroom-playroom which may be used for dining and schoolwork as well. At least 50 percent of the children may use this room. It is located for ready observation and control from the nurses' station and at the same time designed to avoid disturbing patients in their rooms. Furnishings and equipment are selected for multiuse in these various activities.

The dietary facility for the unit is located adjoining the dayroom-playroom to provide convenient and sanitary service of snacks and meals.

The library-classroom is located at the quiet end of the nursing unit, convenient to the adolescent patients.

Waiting and interview rooms are located at the entrance to the unit. This provides an office for the physician and a place where the child's medical history may be reviewed with the parent.

HOSPITALS

Diagnostic X-Ray Suite

By WILBUR R. TAYLOR,
CLIFFORD E. NELSON, M.D., and
WILLIAM W. McMASTER

DIAGNOSTIC X-RAY SUITE

In a recent study it was found that many hospitals allotted inadequate space to the x-ray department, and expansion was often impractical. Adequate space for waiting, toilets, and dressing rooms helps insure continuous routines in handling patients. The lack of adequate space results in needless waste of effort and time in efficiently scheduling examinations. An unsatisfactory layout is a handicap to both the hospital and the radiologist since the hospital loses potential revenue, and the radiologist's time, as well as that of the staff, is needlessly wasted. This is particularly important to a small hospital which has a visiting radiologist for it is to the advantage of the hospital and radiologist to schedule as many examinations as possible during his visit.

Location

The diagnostic x-ray department should be located on the first floor, conveniently accessible both to outpatients and inpatients. It is also desirable to locate the department close to the elevators and adjoining the outpatient department and near other diagnostic and treatment facilities.

The functional requirements of the department are usually best satisfied by locating the x-ray rooms at the end of a wing. In this

location, the activity within the department will not be disturbed by through traffic to other parts of the hospital, and less shielding will be required because of the exterior walls. (See Fig. 1.)

Plan A

Plan A illustrates an x-ray suite that will provide an efficiently operating service for about 8400 patient examinations yearly, or an average of about 35 examinations daily. This average workload is typical in a hospital of approximately 100 beds (or somewhat more) with an out-patient x-ray service. Unforeseen scheduling problems, of course, will occasionally cause the average of 35 examinations per day to be exceeded. (See Fig. 2.)

The staff needed for this volume of work usually includes: 1 radiologist, 2 or 3 technicians, 1 secretary-receptionist, 1 secretary-file clerk, 1 orderly (as needed).

This plan will permit the workload to be augmented at least 50 percent by increasing the staff, if no more than 20 percent of the x-ray work is fluoroscopic.

Among the desirable characteristics that this plan attempts to provide for is the need for correlating the functions of the working group to obtain maximum efficiency. The arrangement of patient areas and examination rooms around the perimeter, with the administrative staff in the center, makes it possible for these units to operate more efficiently. The technicians' corridor in the rear of the department provides for easy access to the x-ray rooms, film processing rooms, and distribution areas without interference from patients' cross traffic.

Administration Spaces

Every radiologist has specific ideas on the most suitable ways for arranging and operating the administrative functions of the x-ray department. Some of the variables involved are assignment of personnel and functions, reception of patients, sequence of patient examinations, film distribution, and staff viewing facilities. This plan provides for flexibility of space arrangements by allowing for variation of several of the operations within the administrative unit.

Waiting Room General waiting space for about ten patients is located at the entrance to the department. From here the patient is directed to an assigned dressing room. A separate area, to the left of the entrance and in sight of the secretary-receptionist, is provided for wheelchair and stretcher patients. This section is partitioned off by a curtain which may be partially drawn to provide privacy, yet afford the necessary surveillance of unattended patients from the secretary-receptionist's desk. Additional chairs in this area can be used to accommodate the attendants of these patients or for an overflow of waiting patients when needed.

Secretary-Receptionist The administrative functions and business records of the department, scheduling of appointments, receiving of patients, typing of the necessary identification forms and requisitions for examinations, and assigning of patients to dressing rooms are handled by the secretary-receptionist. If time permits, the secretary-receptionist assists in typing the radiologist's reports. The desk is centrally located, directly in front of the entrance between the waiting room and administrative area, so that the secretary-receptionist may supervise waiting patients and have access to correspondence and report files.

Secretary-File Clerk The secretary-file clerk assembles, sorts, and files all films and reports, assists the secretary-receptionist when needed, and transcribes and types the radiologist's reports. These functions are not rigidly fixed and can be interchanged, if desired. For example, a technician may be assigned to assist the file clerk with film assembling and sorting, or the file clerk may be given other functions as needed. The desk is located near a counter-partition in the film collection and distribution area. The low counter and the gate (No. 79) are designed so the entrance to the department can be observed and patients directed when required.

Doctors' Viewing Room The doctors' viewing room is located near the office of the radiologist so that he may be immediately available for consultation. The room is near the film files, convenient to the secretary and file clerk, and situated so as not to intrude upon the functional flow of the work. Its location within the administrative unit provides privacy so that diagnostic comments and discussions will not be overheard by patients.

Radiologist's Office This office is conveniently situated near the x-ray rooms, the secretary-receptionist's desk and the filing distribution area, and is not too easily accessible to the public; it is also provided with a door which opens directly to the technicians' corridor. The fire exit which is located off the technicians' corridor provides a second exit from the department for the radiologist.

Film Files The film files are located in the collection and distribution area and convenient to the radiologist's office. Since it is desirable to keep active films for at least five years, approximately 125 linear feet of filing space is provided. After that time, additional storage space elsewhere will be needed for the less active files. Closed front metal x-ray files are recommended (see Fire Safety). Teaching films may not be needed in a hospital of this size, but if desired, a section of the active files may be allotted for this use.

General Facilities

Dressing Rooms Three dressing rooms for each x-ray machine should be provided so that the

HOSPITALS

Diagnostic X-Ray Suite

equipment and staff can function without delay. Each dressing room should be equipped with a straight-back chair, clothes hook, mirror, and a shelf below the mirror. For the protection of patients' valuables, the doors may be equipped with locks, or centrally located lockers may be provided. Where doors are installed, they should swing outward to avoid the possibility of being blocked by a patient and should be at least 12 inches from the floor.

For the convenience of patients in wheelchairs, an outsized dressing room is provided. Instead of a door, it is equipped with a curtain so that the patient can maneuver easily.

Patients' Toilet Rooms Toilets should be immediately available for patients undergoing fluoroscopy, and similar facilities should be conveniently available for waiting patients. A minimum of two toilets should be provided for each x-ray room. All toilets should be located near the x-ray rooms.

At least one toilet room should be directly accessible to each x-ray room and have an opening into the corridor. To prevent the patients from accidentally opening the door between the toilet and x-ray room, this door should be equipped with hardware which is operable only from the x-ray room. The doors of the toilet rooms which open into the patients' corridor should be equipped with bathroom locks, which are operated by knob latch bolts and dead bolts from both sides.

One of the patients' toilet rooms is designed to accommodate a patient in a wheelchair. The room is larger than the others, for easy maneuvering, and has a 3 ft door. The lavatory is set on wall brackets 6 in. out from the wall and 2 ft 10 in. from the floor.

One toilet should be provided with a bedpan flushing attachment. Water closets should be suspended from the wall to simplify cleaning. Each toilet room should be equipped with a grab bar for use by elderly or weak patients. A dome light and buzzer system with an emergency call station in each toilet room and an annunciator at the secretary-receptionist's desk are recommended.

Technicians' Toilets and Lockers During busy periods it is essential that the staff be available at all times. Separate toilet and locker facilities are provided for technicians. This reduces the time technicians must be absent from the area and contributes to the efficiency of the department.

Storage Facilities

General Storage For bulk supplies, a storage cabinet equipped with sliding doors and adjustable shelves is located inside each patients' corridor near the entrance. Materials such as films, opaque solutions, developing solutions, and office supplies are stored here.

Daily Linen Supplies (X-Ray Rooms) Clean linen, requisitioned from the hospital central supply, is stored on a cart (No. 66) in each x-ray room; soiled linen is placed in a hamper (No. 65).

Gown Storage Open adjustable shelves for gown storage are placed next to each general bulk supply cabinet, just inside the corridor entrance. The shelving for clean gowns starts about 4 ft from the floor, leaving space beneath for a linen hamper (No. 65) for soiled gowns.

Janitor's Closet The janitor's closet must be readily available for emergency cleaning and it should be convenient to the x-ray rooms and

toilets. The closet should contain a floor receptor with a curb or a janitor's service sink, a mop-hanging strip and a shelf, and provide space for parking the mop truck.

Diagnostic X-Ray Rooms

X-Ray Equipment Both rooms are equipped with combination x-ray and fluoroscopic machines with spot film devices. An overhead type tube support is indicated in the plan, as this facilitates x-raying a patient in bed or on a stretcher. For reasons of economy, however, it may be desirable to equip one room with a floor-ceiling track. If an overhead mounted track is used, it may be supported from the floor by columns or may be bracketed from the wall, although a ceiling suspension makes a neater installation.

The optimum size of the x-ray room is about 14 by 18 ft. Ceiling height requirements vary for different x-ray machines, but a minimum of 9 ft 6 in. is recommended. The machine and transformer should be placed so as to allow adequate space for admittance of a bed or stretcher in the room. Mounting the transformer on the wall is recommended to save floor space. However, sufficient clearances (at least 2 ft above the transformer) for servicing the transformer should be provided.

The sink and drainboard, for handwashing and rinsing utensils and barium equipment, is equipped with a gooseneck spout. It is located near the foot of the x-ray table. The drainboard can also be used as a barium counter.

It is recommended that the control panel be wired to a signal outside each x-ray room to indicate when the machine is on, to prevent other personnel from inadvertently entering the room. A red light bulb will be satisfactory as a signal for most installations.

Control Booth It is essential that the control booth be located to the right of the machine so that the patient may be observed when the table is inclined, since machines with end-pivoted tables tilt to the right. In the plan, no door is shown on the control booth as the radiation will have scattered at least twice before it reaches the control booth area. This is in accordance with Handbook 60, as amended, issued by the National Bureau of Standards. The arrangement of the control booth to the right and the cassette changer to the extreme left, as shown in the plan, fully meets this requirement. In addition, since the beam is directed toward the outside wall, radiation exposure to other personnel is lessened, and the amount of shielding required is decreased.

If the cassette changers are placed to the right of the machine (on the wall opposite to that indicated on the plan), a door on the control booth or a baffle placed in the room is required to protect the technician in the booth. Furthermore, additional shielding is required to protect films and personnel in the department because the primary beam would not be directed toward the outside wall. In the present scheme, the shielding necessary in the interior walls is principally to safeguard against the scatter radiation.

Storage Cabinet and Writing Counter A storage cabinet (No. 62), with a safety light above, serves also as a writing counter for the radiologist and technicians. Shelves in the cabinet provide space for storage of accessory items such as sandbags, measuring devices used with x-ray machine, and disposable items needed for patients' examinations.

Film Processing and Distribution Area

Darkroom This room is located between the two x-ray rooms to facilitate handling of films. Cassettes are loaded and unloaded on the counter (No. 11). Space is provided for loading and stacking cassettes at both ends of the counter.

A utility sink with a drainboard (No. 24), located opposite the processing tank, is provided for mixing chemical solutions and handwashing. A refrigerating unit (No. 25) for the tank is located in the space beneath the drainboard.

X-ray films are processed in an area separated from the loading counter by a partition (No. 81) at the end of the developing tank which helps to avoid accidental splashing and damage to the screens and films on the loading counter. A through-wall processing unit tank permits the radiologist or staff doctors to read the wet films in the lightroom area without interrupting darkroom procedures.

A lightlock between the darkroom and the lightroom, equipped with interlocking doors, is necessary to allow entrance into the darkroom of other personnel during film processing. Although a maze has some advantages over the lightlock, the additional space needed is not justifiable in a facility of this size. Access panels (No. 22), located in the lightlock and in the control space, are provided to simplify installation and servicing of the processing tanks.

Film Processing Area To reduce unnecessary traffic, the film processing rooms are located near the collection and distribution area. This layout allows the technician to work without interruption during the processing routine. Processing of films begins at the developing tank (No. 26) in the darkroom, and continues to the final rinsing tank (No. 29) in the lightroom where the films may be wet-viewed at an illuminator, if desired, and then dried. After the films are dried, they are brought to the counter (33) in the technicians' corridor for final trimming, and passed through to the film collection and distribution area.

Collection and Distribution Area Film sorting bins (No. 36) are provided above the counter in the collection and distribution area for temporary filing. After all films have been assembled, they are passed through the film pass slot (No. 34) to the radiologist for interpretation. He returns the films in a file cart or through a slot which leads into a box under the distribution counter. The films may then be temporarily filed for viewing by staff doctors or placed in the active files.

Barium Mixing Facilities

A two-compartment sink (No. 75) in a counter, located in the technicians' corridor and accessible to both x-ray rooms, is provided for mixing barium. A duplex outlet for plugging in an electric mixer or a heating element is located above the counter unit. Barium supplies for daily use are stored in cabinets under the counter; the bulk supplies can be stocked in one of the general storage cabinets located in the patients' corridors.

Dark Adaptation

Patients must be allowed to become accustomed to the low lighting level in the x-ray

HOSPITALS

Diagnostic X-Ray Suite

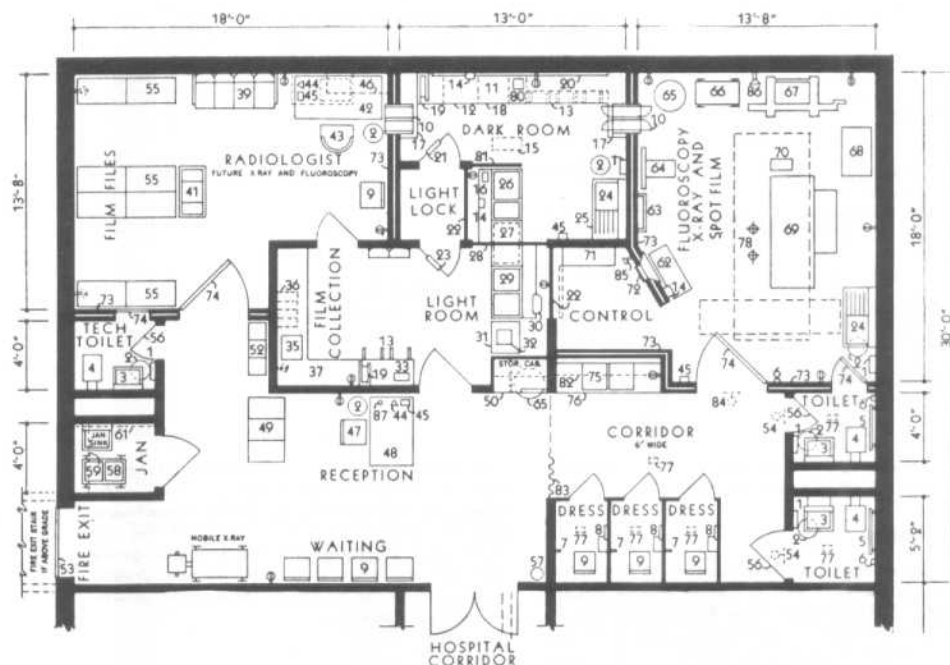

Fig. 3 Diagnostic radiographic suite, Plan B.

rooms and the staff must retain their dark adaptation despite the opening of the doors of the fluoroscopic rooms between patients' examinations.

To facilitate dark adaptation, curtains are shown at the intersections of the technicians' and the patients' corridors. In addition to the illumination normally provided in the corridors, patients' toilet rooms, and dressing rooms, it is recommended that these areas be equipped with an independently controlled dim lighting system of red bulbs for dark adaptation.

Miscellaneous Services

It is assumed that the central sterile supply department of the hospital will provide all such services for the x-ray department.

The mobile x-ray unit should be stored in the radiology department where it will be under the supervision and control of the department and available when needed.

Optional Facilities

Intercommunication System Provision of a system within the department increases the efficiency of the staff and speeds up service. Outlets are shown at the desk of the secretary-receptionist, in the x-ray rooms and the darkroom, and in the technicians' corridor. It is recommended that a one-way intercommunication system, with a microphone in the control booth and a loudspeaker at the cassette changer, be installed so that the technician need not leave the control booth to give instructions to the patient at the far end of the x-ray room.

Refrigerator Some items used in the x-ray department, such as barium suspensions for fluoroscopic examinations of the upper gastrointestinal tract, cream for a gall bladder series, and carbonated beverages for carbon

dioxide distention of the stomach, require refrigeration. The space under one end of the barium counter at the sink (No. 75) in the technicians' corridor may be used for an under-counter type refrigerator.

High-Speed Film Dryer The plan provides sufficient space for an anhydrator, if desired, in lieu of the dryer shown (No. 31).

Finish Materials

Materials used in this department are generally similar to those usually provided in hospitals. However, special attention should be given to some of the areas in the x-ray suite.

Darkroom The cassette loading counter surface should be of a material which is static-free; wood or linoleum is often preferred. Vinyl or vinyl-asbestos tile, $\frac{1}{8}$ in. thick, appears to be a satisfactory material for floors in this size department. Experience indicates, however, that asphalt tile and linoleum floors do not stand up well under the effects of spilled solutions. A pattern of alternating dark and light tiles improves visibility when working under a safe light.

X-Ray Rooms No special finishes are required for the x-ray rooms. Asphalt tile floors are satisfactory and a pattern of alternating dark and light tiles is also desirable here. Plaster walls and ceilings are acceptable, but acoustical tile ceilings are preferred since they aid in reducing reverberation.

Toilets Tile floors and wainscot are highly desirable for easy cleaning.

Doctors' Viewing Room Acoustical treatment is recommended to lessen the possibility of doctors' conversations being overheard by nearby waiting patients.

Electrical Installations

Voltage supplied to the x-ray unit should be constant so that fluoroscopic images and radiographs will be uniform. An independent feeder with sufficient capacity to prevent a voltage drop greater than 3 percent is recommended. To minimize voltage fluctuations, a separate transformer for the x-ray feeder is required for most installations.

Illumination

Illumination intensities in the various areas of the suite should comply with recommendations given in the Lighting Handbook, 3rd Edition (1959), published by the Illuminating Engineering Society. Briefly, the general illumination should be not less than 10 footcandles in corridors and in rooms where reading is not required. The waiting room should have 15 footcandles, with supplemental lighting for reading. Offices and areas where clerical work is performed should have at least 50 footcandles, preferably 70.

Indirect or cove lighting fixtures are recommended for the x-ray rooms so that patients need not be inconvenienced by glare when lying face upward during examinations.

Primary barriers should be provided on all surfaces of the x-ray rooms which are exposed, or which may be exposed, to the useful beam between the x-ray tube and occupied areas. Secondary barriers should be provided on all other room surfaces where protection is needed. In determining secondary barriers, consideration should be given to direct or leakage radiation which passes through the tube housing, and also to the secondary or scattered radiation emitted from objects being irradiated by either the useful beam, leakage radiation, or other scattered radiation.

Air Conditioning

Air conditioning with positive ventilation and a well-defined pattern of air movement within the department is necessary to provide an acceptable environment. In order to prevent the spread of odors from the radiographic and fluoroscopic rooms, darkroom, toilets, and janitor's closets, the ventilation system should be designed so that a negative air pressure relative to the adjoining corridors will be maintained in these rooms. This can be done by exhausting more air from these rooms than is supplied to them, and by reversing this procedure in the corridors. Doors to the toilets and the janitor's closet should be undercut or louvered so that air from the corridors may flow into these areas and be exhausted without recirculation.

Because of the odor problem, the air from the fluoroscopic and x-ray rooms should not be recirculated during the time these rooms are in use, unless adequate odor removal equipment is incorporated in the ventilation system. For economical operation, where odor control equipment is not used, the exhaust system should be provided with motor-operated dampers, switched from within the room, which will direct the air to the outdoors when the rooms are being used, or recirculate the air during idle periods.

As the darkroom will be used for longer periods than the x-ray rooms, an independent system to exhaust the air to the outdoors should be provided. The exhaust from the darkroom should be controlled from a switch in the room and the system should be dam-

HOSPITALS

Diagnostic X-Ray Suite

Fig. 4 X-ray department. (a) Before expansion. (b) After expansion.

pered to regulate the amount of air handled. The exhaust from the film dryer in the light-room should be connected into the darkroom exhaust system.

The following conditions are recommended for the comfort of patients and personnel:

Administration and Waiting Areas A temperature of 72° F with a relative humidity of 50 per cent and a ventilation rate of 1-1½ air changes per hour.

Patients' and Technicians' Corridors A temperature of 75° F to 80° F with relative humidity of 50 per cent and a ventilation rate of 2 air changes per hour.

Fluoroscopic and X-Ray Rooms A temperature of 75° F to 80° F with relative humidity of 50 per cent and a ventilation rate of 6 air changes per hour.

Darkroom A temperature of 72° F with rela-

tive humidity of 50 per cent and a ventilation rate of 10 air changes per hour.

Fire Safety

To provide an adequate measure of fire safety for the patients and the staff in this department, consideration must be given to factors of design and construction relating to fire prevention and fire protection. The basic structure should be built with fire resistive materials and incombustible finishes and provided with approved equipment.

Closed metal files are recommended for storage of x-ray films. If open shelves are used instead, an automatic sprinkler system should be installed over this storage area to neutralize the hazard of the large volume of combustible materials which would be exposed to possible fire.

Fire extinguishers (carbon dioxide type preferred) should be provided, as located on the plans, to assist in controlling fire.

In accordance with good fire safety practice, two means of egress are provided in the plan: one at the entrance to the department and an emergency exit located off the patient's corridor (door No. 53). The emergency fire exit should lead directly to the ground level outside the building, through an appropriate exit stairway.

Plan B—Design for Expansion

This one-machine department, designed to handle a daily average of about 20 patient examinations, could satisfactorily serve a hospital of 50 to 100 beds, depending upon the extent of outpatient services provided. As in Plan A, its volume of examinations can be increased, depending on the staffing pattern and other factors, discussed previously. (See Fig. 3.)

The staff usually required for this work-

26. Airflex biplane control

Fig. 6 Typical vascular layout. Equipment shown dotted is for future installation.

load includes: 1 part-time radiologist, 1 technician, 1 secretary-receptionist-technician, 1 orderly (as needed).

This plan will result in a functional unit. It has another important advantage in that it may be expanded to include all the features of Plan A. Such expansion is usually indicated when the hospital is served by a full-time radiologist, when the average daily load approaches 30 examinations per day, and when the proportion of time-consuming examinations becomes high.

Expansion problems frequently occur in a hospital of 100 beds or less, where there is only one x-ray machine and a part-time radiologist. As the volume of work increases, the radiologist spends more time at the hospital, and a second machine is installed. Unfortunately, in most of these cases, the lack of

planning for a future expansion program and expansion area results in an inefficient layout. This limits the usefulness of the equipment and the efficiency of the staff. Examples of such limitations are: poor location of the darkroom in relation to the new x-ray room, inadequate size of the darkroom, insufficient number of toilet facilities and dressing rooms, lack of office and waiting areas, and limited film filing space.

Remodeling an x-ray department is more expensive than remodeling other areas of a hospital because of the shielding, wiring, and plumbing. Expansion of the x-ray department should be incorporated in the original plan. Roughing in the plumbing and building in the shielding and electrical conduits in the expansion space will result in future savings and an efficient x-ray suite.

Minimum alterations to Plan B necessary to duplicate the facilities of Plan A would be the remodeling of the film collection area to accommodate a new control booth, the elimination of the partition between the lightroom and reception space, the elimination of the dressing rooms and of the partition behind them.

Until the need for remodeling becomes apparent, part of the administration offices of the hospital may temporarily be situated in the expansion space. When enlarging the x-ray department, other space may then be added to the administration department. The dotted lines on Fig. 4 illustrate how this expansion may be designed.

A typical radiographic room is shown in Fig. 5; a typical vascular layout is shown in Fig. 6.

Teletherapy Units

By WILBUR R. TAYLOR,
WILLIAM A. MILLS, and
JAMES G. TERRILL, JR.

DESIGN OF TELETHERAPY UNITS

Radiation and Architectural Considerations for Cobalt-60 Unit

By the term teletherapy, we are restricting ourselves to the use of radiation at a distance; that is, the subject and source are separated by a distance of 50 centimeters or more. In particular, we are concerned with the use of the radioactive isotopes cobalt-60 and cesium-137 as sources of radiation in teletherapy units.

We have restricted our discussion to ^{60}Co and ^{137}Cs , primarily because they are the more familiar of the isotopes suggested for use in teletherapy units. We are not including the use of radium and high energy x-rays, since some of the problems associated with these are quite different in their solution and nature.

The primary purposes of this article are to furnish architects who are anticipating a teletherapy unit with information on basic radiation protection ideas and techniques, and to serve as a guide in the solutions of certain architectural problems. We are by no means attempting to evaluate the advantages and disadvantages of ^{60}Co and ^{137}Cs units against other types of units.

For a discussion of the fundamentals of radiation shielding and a glossary of radiation terminology, see *Architectural Record*, November, 1957, pages 218-220.

In planning a cobalt installation, it should be understood that each type of machine and its location within the building will present a different problem which will require an individual solution. Consequently, no one type plan can be designed which will take care of the various shielding requirements presented by the different machines and installations. The architect is dependent upon other professionals for specific technical information he needs before he can intelligently design a building containing a cobalt teletherapy unit. The problems incurred may materially affect the orientation, location, and structural and functional design of the building. Therefore, during preliminary design stages, close cooperation between architect, radiologist, and radiation physicist is necessary to develop an efficient and economical layout.

It should be noted that the Atomic Energy Commission places responsibility upon the applicant for conditions of installation and use of the facility. Since the use of a facility is largely dependent upon the conditions of installation, it is to the applicant's advantage to secure the services of a radiation physicist at the inception of a project. His function is to advise the applicant and architect on radiation

requirements, assume responsibility for the final design as to shielding provided and furnish the supporting information required in Application Form AEC-313 relative to exposure rates in areas surrounding the teletherapy room and occupancy factors assigned.

Fundamental decisions as to: (1) the type of machine, (2) strength of the source, (3) desired location, and (4) the shielding required for floor, walls, and ceiling must be made before the building's structural system can be designed. During the early design, it may be determined that the structural system cannot support the weight of the shielding, or perhaps soil conditions will not permit sufficient excavation for a subgrade installation. It may then be necessary to change or alter one or more of the following: the machine or its operation, the source strength or the location of the room.

To those not familiar with such shielding problems, the included plans have been developed to illustrate the shielding necessary for three types of machines in specific locations. However, before considering the detailed plans, it may be desirable to discuss some of the general requirements of such facilities.

Location

The cobalt suite should adjoin the x-ray therapy department. This location permits the joint use of waiting, dressing, toilet, examination, work and consultation rooms. In addition, it offers the important advantage of having the staff concentrated in one area, thereby eliminating the considerable loss of time involved in traveling to a remote location. This is an important consideration and justifies the cost of any additional shielding that may be necessary to achieve it.

A location below grade, unoccupied above and below, will require less shielding. However, if such a location separates the cobalt and the x-ray therapy departments, it may be more costly in both loss of staff time and efficiency than the cost of concrete shielding amortized over several years. If, for example, twenty-five minutes per day are lost in traveling to a remote location, one additional patient could be treated in this time each day—or 240 patients per year. Assuming a staff salary of \$20,000 per year, this loss of twenty-five minutes per day results in an indirect salary loss of \$1032 per year, which would soon equal the cost of shielding in a new facility.

A corner location for the cobalt room is usually desirable since through traffic is eliminated, only two interior walls require shielding, distance to the property line utilizes the inverse square law to reduce shielding and the structural requirements are more easily solved.

Teletherapy Room Details

Size The room size may vary to suit different manufacturers' equipment. A room approximately 15 ft by 18 ft by 9 ft-6 in. plus the necessary entrance maze, will accommodate most of the machines commercially available with the exception of the largest rotating models. For reasons of cost, the room should be as compact as possible after allowing space to install the equipment and to position the treatment table.

Shielding The shielding necessary for a room must not only be considered in terms of floor, ceiling and wall shielding, but also such things as doors, windows, ventilation and heating ducts, and safety locks. Radiation that might

escape through such possibilities could result in overexposure to personnel, if proper precautions are not taken.

Entrance The primary purpose of specific entrance construction is to protect personnel. It should also provide sufficient space to admit a stretcher and the largest crated piece of equipment. In some cases, a considerable savings in cost of assembling equipment may be had by making the door and maze large enough to admit the crated assembled machine. For this purpose, some manufacturers specify a door opening of 4 by 7 ft and a minimum distance of 6 ft at the end of the maze.

Rather than add large amounts of lead to doors, the shielding problem may be solved to some degree by having the door to the teletherapy room open into a maze. This maze should be built so that no primary radiation could fall directly on the door. In designing doors for such a room, a good practice is to have a door of wood with a layer of lead. This lead can either be on the inside surface, or between layers of wood. Commercially available x-ray doors serve well for this purpose. The space between the door and floor can usually be shielded by using a lead strip under the door or by making a slight rise in the floor containing lead, on the outer side of the door. Lead shielding at the jamb and head between the frame and buck may be eliminated by the use of a combination frame and buck set in concrete.

For safety precautions, the door lock should be such that the door can be readily opened from inside the cobalt room.

Control View Window It is standard practice to locate this window at a height which will permit the operator to be seated during the treatment period, 4 ft-0 in. from the floor to the center of the window being an optimum distance. In plan, the window should be located in the area of minimum radiation and for convenient observation of the patient. This position, for a rotational machine, would be along the axis of rotation, and for a fixed beam unit, 90° to the plane of tilt.

From the control view window the entire room should be in full view, using mirrors when necessary. The glass should contain lead or other materials in amounts which would provide shielding equivalent to the surrounding concrete. The frame is usually packed with lead wool and should be designed to offset the shielding loss of the reduced concrete thickness at beveled areas. The cost of such special glass and frame increases rapidly with size and an 8 by 8 in. window is considered an optimum size.

Heating and Air Conditioning The only problem in relation to heating and air conditioning not encountered in other buildings is that of providing shielding where walls are pierced with supply and return ducts. The usual solution is to locate ducts and openings in walls which are least subject to radiation and offset the path of ducts through the wall, lead or other high density material being added, where necessary, to maintain the shielding value of the wall displaced by ducts.

Electrical Electrical service required for the machine will vary with each manufacturer's equipment. Voltage will vary from 110-single phase to 220-three phase for large machines.

Room lighting should assure good over-all illumination, preferably from cove lighting or an indirect type of fixture. It is essential

For Design Requirements see previous page.

A primary beam absorber on a machine reduces the shielding requirements considerably. However, some radiologists prefer to use a machine without the absorber, because of its greater flexibility, and for this reason some machines are designed to be used with or without the absorber. Under these conditions the room shielding should be designed for use either way. The plan and section shown here illustrate the necessary shielding.

Plan of Cobalt-60 Room

Section AA

HOSPITALS

Electroencephalographic Suite

that the operator be able to observe any movement of the patient during treatment and shadows produced by a rotating machine interfere with observation.

In providing a safety lock for the door, it has been found of great value to interlock the machine control with the door, so that opening the door automatically shuts off the machine.

Conduits should be provided for power and control wiring.

Environment The general effect to be created in this department should be one of cheerfulness and restfulness. Color and even murals have been used effectively on the walls of the cobalt room.

The usual hospital finishes such as acoustical ceiling tile and resilient flooring are desirable in this area.

Remodeling Unless previously designed for super voltage x-ray, remodeling an existing building can be expensive. It is often impossible to build in sufficient shielding which makes it necessary to control nearby occupancy and restrict direction of the beam, thereby handicapping the usefulness of the machine. Other problems such as relocating plumbing, heating, electrical services and disturbing the normal operation of the building during remodeling must be considered.

In new construction, concrete shielding is relatively cheap, but in remodeling the cost is high. For this reason the use of masonry units may be preferable since no form work is necessary and the work can be performed intermittently. Good workmanship, of course, is necessary to prevent voids in mortar joints.

In some cases it might be better to add to the building, rather than to remodel an existing portion. Normal hospital operation would not be interfered with, costs may be lower and a more efficient layout would probably result.

By NOYCE L. GRIFFIN, Electrical Engineer, Architectural and Engineering Branch, Division of Hospital and Medical Facilities, Public Health Service, U.S. Department of Health, Education and Welfare.

ELECTROENCEPHALOGRAPHIC SUITE

Introduction

An electroencephalographic (EEG) examination consists of the measurement of electrical potentials of the brain as measurable at the scalp. It requires an extremely sensitive instrument located so as to be as free as possible from outside electrical disturbances. The examination requires careful preparation of the patient and involves securing several pairs of electrodes to the patient's scalp, connecting the conductors from the electrodes to the EEG unit, operating the EEG unit to obtain recordings under definite physical conditions of the patient, removing the electrodes and any adhesive, if used in attaching the electrodes.

Suitable space must be provided for the neurologist and his staff to examine patients, read the recordings, prepare reports, and keep records. The suite should be arranged to provide office facilities for the neurologist and typist or secretary, a workroom for technician,

space for preparation and examination of patients, and storage space for supplies and voluminous EEG recordings. The preparation and examining space should, as a minimum, comprise two rooms: one with a hospital-type bed and equipment for the preparation of the patient; the other containing the EEG instruments, a desk or table, and other facilities needed by the technician (Fig. 1). A more efficient layout may be had by dividing the preparation and examining space into separate rooms. This would increase the patient-handling capacity of the unit, as one patient could be prepared while another is examined (Fig. 2). Toilet facilities should be conveniently available for patients' use.

Although shielding of the patient's room against electrical disturbances is not always required, it is usually desirable. Where such disturbances are excessive for the quality of work required, a completely shielded room may be necessary. The most common electrical disturbances are caused by high-frequency equipment such as diathermy and radio, static electricity, high-voltage transmission lines, large transformer banks, large motors, nearby powerful FM broadcast stations, and conductors carrying heavy currents. To minimize disturbances from power systems, all power conductors in the vicinity of the EEG machine should be metal armored or installed in metal raceway. Large or main electrical conductors should be routed as far away from the EEG examining locations as practicable, both horizontally and vertically, and use of fluorescent lighting in the vicinity of the EEG unit should be avoided.

A reasonable amount of soundproofing of the examining room is desirable.

EEG recordings and case records are bulky and require considerable space for filing. Open shelving of the large pigeonhole type is reasonably satisfactory for filing the large folders of active case records. This filing space should be located in the office or preferably in an adjacent room convenient to the neurologist.

Workroom

The workroom facilities and equipment normally consist of the EEG unit, preferably the console type, photo-stimulator panel, a supply cabinet for recording paper, preparation materials, an electric clock with sweep second hand, a workbench with wood top and cabinet below for EEG maintenance and general use, and a general office-type desk or table. Switches for control of lights in workroom and examining room should be located in the workroom. Shelving for EEG recordings and case records may be located in this room unless other suitable space is provided, and should be approximately 12 in. deep.

Examining Room

Doors through which patients must pass to enter the examining room should be 3 ft 10 in. wide to permit easy passage of stretcher or wheelchair. The size of the examining room should be sufficient to accommodate a hospital bed and allow enough additional space to permit the technician to work efficiently. For sleep inducement, exterior windows should be equipped with shades to partially darken the room. As it is desirable that the patient be in full view of the operator, the examining room should have sufficient width to permit the bed to be placed parallel to the wall nearest the workroom. This wall should have two 3-in.

openings, 20 in. above the floor, one for passing the EEG electrode cable with plug attached, the other for passing the photostimulator conductors.

The partition between the workroom and the patient's room should be provided with a glass window not less than 24 in. high and 36 in. wide, mounted with the lower edge 43 in. from the floor. This window should be located to provide good vision of the patient. In the preparation area, floor and sink are subjected to staining and eroding effects of chemicals such as acetone and collodion used for setting and removing electrodes to and from patient's scalp. The sink should be vitreous china set in a countertop resistant to acid and alkali, with cabinets below.

A masonry-type floor such as tile or terrazzo is recommended in the preparation area. Solvents such as acetone used for removal of electrode adhesive, when spilled or dropped on the floor, are injurious to the resilient type of flooring materials such as vinyl, asphalt, rubber, or linoleum.

When air-drying paste is used in setting electrodes, means should be provided for quick drying. Hand-held hair dryers are sometimes used, but a low-pressure compressed-air outlet is preferred. Some technicians use a self-supporting conducting paste for electrode attachment that requires no drying; others use pin-type electrodes, which do not require paste or adhesive, for insertion into the scalp.

Shielding

Shielding may be required, depending upon the equipment used and its location with respect to sources of disturbances and the quality of recordings required. It is recommended that in new construction shielding be provided in all examining rooms, and that omission of shielding be considered only when converting existing rooms.

Properly installed shielding of the examining rooms will eliminate or minimize outside disturbances caused by static electrical discharges and high-frequency equipment. It has little effect on magnetic disturbances such as those produced by power transformers, high-voltage equipment, and current-carrying conductors. For minimizing disturbances due to magnetic forces, the most effective means is distance.

Where shielding is required, panels and equipment for completely shielding the room may be obtained from several manufacturers, or as an alternate, satisfactory shielding may be constructed with copper insect screening. The strips of shielding material should be bonded and soldered at intervals of about 2 ft or less and should entirely cover all walls, floors, ceiling, doors, and windows. The screening should pass on the room side of any lighting fixture or electrical device without making contact with it. Wall and ceiling finish materials and the floor covering may be applied over the shielding if desired. In this case, the shielding material should be copper sheeting to preclude the possibility of interferences developing in the shielding due to the installation of plaster or mastic materials.

The shield should be grounded at one point only. The ground connection should be brought out to a terminal arrangement convenient for connection to the EEG unit and for disconnection for testing. Double screening produces a more effective shield than single screening. Shielding efficiency is further increased by insulating one layer of screen from the other

PHYSICAL THERAPY DEPARTMENT*

Of the many environmental factors which condition the effectiveness of physical therapy service to patients, the most important are

*This material is condensed from the chapter "Suitable Environment" in the manual *Physical Therapy Essentials of a Hospital Department* prepared by the Joint Committee of the American Hospital Association and the American Physical Therapy Association.

Planning is by Thomas P. Galbraith and Peter N. Jensen, Hospital Architects of the Architectural and Engineering Branch, Division of Hospital and Medical Facilities, Public Health Service.

space, location and work areas. Ventilation, lighting, interior finish and related considerations also contribute toward providing a suitable environment. The keynote is function.

Location

Location is closely related to function. The area selected for physical therapy should be centrally located to minimize problems of transporting patients and to facilitate giving bedside treatment when necessary. At least half of the patients treated in a general hospital physical therapy department are likely to be out-patients. With this in mind, special attention should be given to accessibility, and to having as few steps as possible to climb, as few long corridors and heavy doors to negotiate. A ground floor location, convenient for both in- and out-patients and for access to an outdoor exercise area, is recommended.

Availability of daylight and fresh air should also be considered in selecting a location.

In new hospitals, physical therapy is frequently placed in an area which includes other out-patient services, social service, occupa-

tional therapy, recreation. It is particularly important that physical and occupational therapy be in close proximity.

Amount of Space

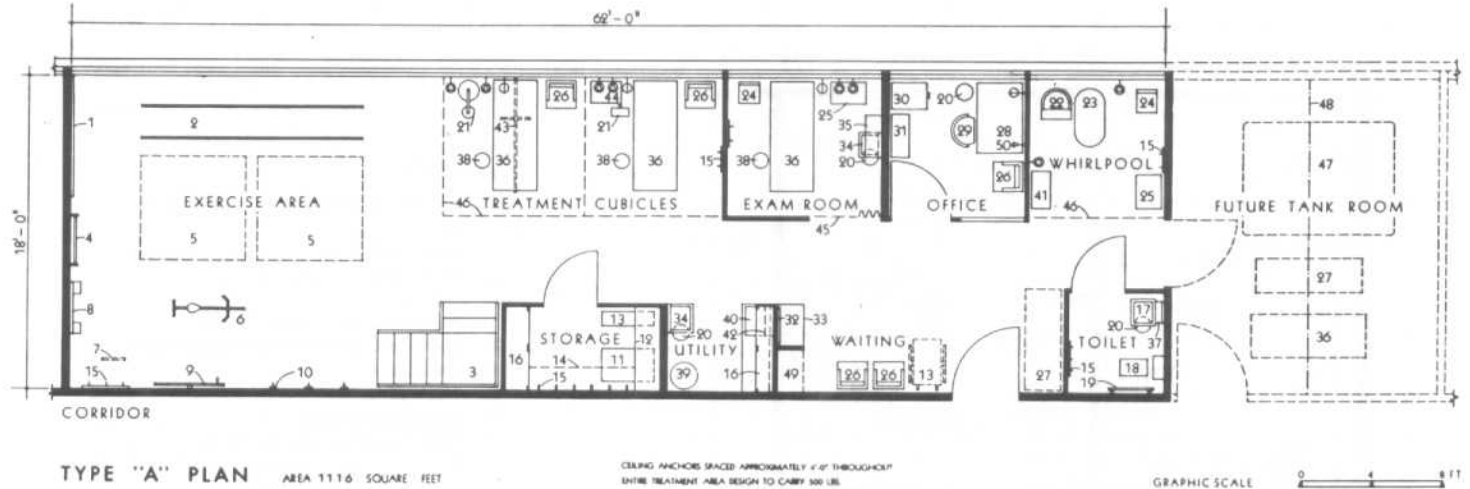

The amount of space needed depends on the number of patients treated, the kinds of disabilities and the treatments required. Also to be considered is the fact that some space-consuming equipment—such as a whirlpool bath, treatment tables, parallel bars, etc.—are minimum essentials for even a one-therapist department. These pieces of equipment will not be multiplied in direct proportion to increases in staff and patient load.

Efforts to correlate bed capacity and physical therapy space requirements are not satisfactory. Hospitals with 50-100 beds may serve large numbers of out-patients. The amount of space given over to physical therapy in a small hospital is, justifiably, out of proportion to the bed capacity.

No absolute standard can be recommended as the amount of space needed for physical therapy in a general hospital. The most that

Physical Therapy Department

can be said is that, if possible, it is desirable to plan for at least a thousand square feet of floor space, free of structural obstructions. About half of that should be exercise area. (See Fig. 1.)

This does not mean that a hospital cannot begin an effective physical therapy service in smaller quarters. Many have done so successfully, using to full advantage whatever space resources they had. But crowded quarters do subject the staff to strain and call for more than ordinary ingenuity and good humor in order to make it possible for patients to obtain maximum benefit from treatment.

Work Space Components

Whatever the eventual size of a physical therapy department, from the very beginning plans must be made to provide certain kinds of work space. These essential components can be expanded, multiplied or refined as the physical therapy department grows but the fundamental requirements are the same for a small or large department. They include: (1) reception area, (2) staff space, (3) examining room, (4) treatment areas, (5) toilet facilities, (6) storage.

Experienced physical therapists have many suggestions for increasing the efficiency of physical therapy departments by giving attention to details of planning and arranging these component work areas. For example:

Reception area: Accommodations for in-patients and out-patients, if possible. Adequate space for stretcher and wheelchair patients.

Staff space—private: Office space suitable for interviewing patients, attending to administrative and clerical duties, housing files, etc. Writing facilities for the staff adequate for dictation, record keeping. There should be space

for staff lockers and dressing rooms separate from the patient area, either within the department or near to it.

Examining room: Floor to ceiling partitions for privacy. Arranged so that necessary examining equipment can remain in the room permanently. Possible to use this space for special tests and measurements or for treatment when privacy is desirable.

Treatment area: There are three types of treatment areas: cubicle (dry), underwater exercise (wet) and exercise (open). Each is designed to meet the particular requirements of the special equipment used for different kinds of treatment.

Cubicle: Each unit large enough for the physical therapist to work on either side of the table without having to move equipment belonging in the cubicle. Preferably cubicles divided by curtains for easier access for wheelchair and stretcher cases, for expansion of usable floor area for gait analysis, group activity or teaching purposes.

Curtain tracks should be flush with the ceiling and curtains should have open panels at the top for ventilation when drawn. Both curtains and tracks should be sturdy. In or near the cubicles, out-patients need a place or locker for their outer clothing.

Underwater exercise area: All equipment requiring special plumbing and water supply concentrated in one section of the department but accessible and adjacent to other treatment areas. Should include a treatment table, especially in the room with a tank or exercise pool. Fixed overhead lifts are absolutely essential for the efficient use of tanks and failure to provide lifts severely limits the usefulness of this valuable equipment. Plumbing and other installation requirements, humidity and noise

from motors call for special care and attention. Electrical and metal equipment in other treatment areas may suffer damage unless the underwater exercise area is carefully planned.

Exercise area: Very flexible open space planned to accommodate patients engaged in diverse individual or group exercise activities. Used extensively by people in wheelchairs, on crutches or canes, or with other disabilities which limit their motion and agility. At least one wall should be reinforced for the installation of stall bars and similar equipment (see Fig. 2).

Toilet facilities: Separate toilet facilities for patients and staff, if possible. Patient facilities should be designed to accommodate wheelchair patients. If the department serves small children, seat adaptors with foot rests should be provided.

Storage: Designed to meet special needs in and near work areas. Should also be storage space on the wards for equipment and supplies usually needed for bedside treatments. For wheelchairs, stretchers, etc., it is best to plan "carport" space, not closets. All storage space should be accessible, simple, well lighted.

Special Considerations

Ventilation Adequate, controlled ventilation is of extreme importance in a physical therapy department. Many of the treatment procedures require the use of dry or moist heat, or active exercise, which raise body temperatures. A continuous, reliable flow of fresh air is essential to the comfort of patients and staff. This includes protection from drafts.

Air conditioning, desirable for the entire department, will be a necessity for certain areas of the physical therapy department, in most

Perspective sketches
by William McMaster

Fig. 2

HOSPITALS

Occupational Therapy Department

sections of the country. The reduction of humidity for comfort, protection of equipment and reduction of the hazard of slippery floors makes air conditioning vital in the underwater exercise area. It has been demonstrated as desirable in the exercise area and in treatment cubicles, especially where heat producing equipment is used. Air conditioning engineers should be consulted before ventilation equipment is installed.

Sinks Hospitals hand washing lavatories with hot and cold water mixing outlets, preferably foot operated, should be located at the proper height in convenient places. At least one sink should be of sufficient width and depth to accommodate the care of wet packs and other special washing needs.

Interior Finishes The activity of patients in wheelchairs, on stretchers and crutches subjects floors and walls to heavy wear. Materials which will stand up under such rough usage, remain attractive and require a minimum of maintenance should be specified despite higher costs.

All interior wall surfaces of the department should have a durable and attractive wainscot to protect them against damage by wheelchairs, stretchers and carts. Ceramic wall tile or glazed structural units will serve the purpose but they emphasize the institutional character of the hospital. In patient areas this should be minimized as much as possible. In the last several years vinyl wall covering has gained in popularity as a wainscoting material, and to some extent for the entire wall. Two weights of the material are available; the heavier weight for areas subjected to severe abuse, the lighter weight for other parts of the wall.

The use of decorative colors for interior finishes and equipment is, of course, highly desirable in this department as it is in other parts of the hospital. Research in "color therapy" for hospitals adds to decorators' ideas the therapeutic value of combinations of pastel colors. "Cool" pastels—green, blue, violet and their many derivatives—are considered mildly restful. Some light colors in general are stimulating and may be of advantage in the exercise area.

Doors For accommodation of stretcher and wheelchair traffic, doors within the department should be at least 40 inches wide. Raised thresholds should be eliminated.

Ceiling Moorings These moorings, strategically located in the ceiling in treatment areas, have been found useful for attaching overhead equipment such as hoists, pulleys, bars, counter balancing equipment, etc. They should be constructed and attached to joists in such a manner that each supports at least 500 pounds.

Layout

It is impossible to anticipate all of the practical problems of layout in a particular building or to say in advance that one plan or another is the right one. A few guidelines, however, may be useful in making decisions about layout.

Expect to expand and plan for it from the beginning. It is impossible to overestimate the value of the exercise area. Give it as many square feet of appropriate space as possible.

Note the need to have the underwater exercise equipment grouped in one area, separate but adjacent and accessible to the other treatment areas.

When deciding which units to place next to each other or group together, consider how

they are used by patients, especially the flow of traffic from one unit to another. Try to avoid needless traffic. Try to conserve the energies of staff.

Visit other physical therapy departments and find out what the physical therapists like or would like to change in the layouts of their own departments.

By ALONZO W. CLARK, AIA with the collaboration of the American Occupational Therapy Association

OCCUPATIONAL THERAPY DEPARTMENT

The increasing recognition of occupational therapy as an integral part of the medical rehabilitation program has resulted in its becoming an increasingly important element of hospital planning.

These pages present a summary of the recommendations of the American Occupational Therapy Association on the planning of typical occupational therapy departments. These basic plans and discussions were developed to serve only as guides for designing similar units, and will not be universally applicable without some modification. This material was presented at length in the October, 1950, issue of *HOSPITALS, Journal of the American Hospital Association*. For reprints of this article, which contains extensive equipment and supply lists for planning storage, write American Occupational Therapy Association, 6000 Executive Blvd., Suite 200, Rockville, MD 20852.

Basic solutions for occupational therapy departments are largely dependent on the following factors:

1. **Number of patients to be treated.** On the basis of hospital surveys and committee recommendations, it was agreed that 30 per cent of hospital patients should normally be referred for occupational therapy. About 40 per cent of these would be treated in the clinic, and 60 per cent treated in their beds or on the wards. One occupational therapist in the clinic can generally accommodate about 15 patients in each of two daily sessions, one in the morning, one in the afternoon. This number will vary according to the type of patient—more psychiatric patients, fewer physically disabled patients.

2. **Floor space required by patients.** Approximately 54 to 61 sq ft per patient is recommended for the entire department, including clinic, office and storage. For the clinic alone, 42 to 47 sq ft per patient is suggested to allow for easy circulation and use of equipment. These figures are based on a study of the needs of a typical department.

3. **Types of treatment media to be used.** Some 70-odd activities are used in occupational therapy departments throughout the country. Basic requirements for small units are as follows; these should be expanded for larger units:

- a. **Bench work**—carpentry, plastics, metal work including painting and finishing of completed projects.

- b. **Table work**—leather, blockprinting, fly-tying, sewing and art work.

- c. **Loom work**—weaving, braiding.

- d. **"Functional equipment"** (not an active classification)—bicycle, jig saws and other adapted equipment for treatment of physical disabilities.

Storage facilities should provide for at least 3 months' supply, as many institutions order on

a quarterly basis. All the above items must, of course, be adapted to suit a particular type and size of hospital.

4. **Location of the department in a hospital.** Daylighted space as close to patient areas as possible and readily accessible to toilet facilities is recommended. Proximity to the physical therapy department is advisable. Necessary facilities include running water, gas, and electric outlets; dust collectors for power wood-working tools are recommended.

The Smaller Unit

For hospitals up to a 250-bed capacity, a basic plan was evolved (see next page). At the rate of referral cited, up to 30 patients should be accommodated. These could be cared for by one therapist, with a possible second therapist for ward service. On the basis of 15 patients per session at 54 sq ft per patient, the entire unit was allotted 813.75 sq ft (17 1/2 by 46 1/2 ft). The clinic area, planned at 42 sq ft per patient, totals 638.75 sq ft (17 1/2 by 36 1/2 ft). The minimum basic activities were provided for with 20 work stations for flexibility in selection. Activities requiring bulky equipment such as printing and advanced ceramics were omitted. It was assumed that preparation and finishing could be done in the clinic or on a counter top in the storeroom. The following considerations were made for the three specific areas within the department:

1. **Clinic area.** The first obvious requirement is space for free circulation around the required equipment (see general list following). Space for parking at least 3 wheel chairs is also necessary. Double doors at shop entrance simplify moving equipment and supplies. Sliding doors for upper cabinets avoid interference with patients working at counter tops. No display case for finished articles was included as it was felt that this emphasized the product rather than therapeutic objectives.

2. **Storage area.** Space was provided for a mobile cart for servicing ward patients. A cabinet with work top was included for preparation and finishing work. It was assumed that only 8-ft lengths of lumber and plywood would be stored in this basic unit, and that other closets, rooms, etc. in various parts of the hospital could be used for "dead storage."

3. **Office area.** Space was provided for the usual office furnishings. A large glass panel in front of the desk facilitates control and supervision of the unit.

Variations for Hospital Types The basic plan is directly applicable to *psychiatric and general medical and surgical hospitals*. In the latter case, a bicycle jig saw is recommended in place of a drill press stand (a table model drill press could be used).

Tuberculosis hospitals require two minor changes: replacement of one floor loom and the braid-weaving frame with two industrial sewing machines.

Pediatric hospitals need the following changes: a plan adaptable to division into two parts—one for small children, one for adolescents. For equipment changes, see plan. Tables should adjust in height.

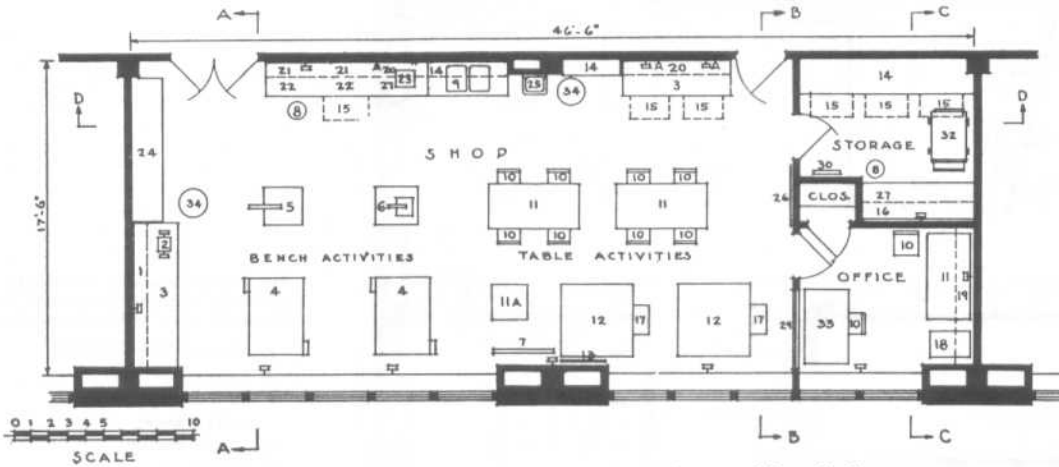

Physical disability hospitals can use the basic plan with a few variations in equipment. Although fewer patients can be treated per therapist, fewer will be able to come to the clinic for treatment; a second therapist will be needed for treatment in the wards.

The Larger Unit

A basic plan for a typical occupational therapy unit for large hospitals of approximately 500

beds was shown previously. Again using the same basis for rate of patient referrals to the department (30 per cent of rated bed capacity), the large unit should accommodate 150 patients a day. The actual clinic load would be 60 patients (40 per cent of 150), or about 30 in each of two sessions.

The unit as presented was planned on the basis of 31 patients. Using 61 sq ft per person, the gross area allotted the entire unit is approximately 1,880 sq ft. Net area of the clinic is about 1,450 sq ft, or 47 sq ft per person.

This increased space per person over that allowed in the smaller unit is the result of adding two activities requiring bulky equipment and separate rooms. These are ceramics and printing. It was also deemed essential to have a separate ward preparation room to serve the increased number of ward patients. To allow for a necessary dispersion factor, 10 extra work stations are provided in the clinic. The larger unit therefore contains the following sections:

1. *Clinic*, including weaving and table activities area, bench activities, printing unit, ceramics unit.

2. *Office*.

3. *Storage*.

4. *Ward preparation area*.

Three therapists plus three assistants could run clinic and wards.

Space requirements for the various activities were determined from the following estimate:

Activity	% of patients	No. of patients
Wood, plastics, metal.	22	7
General crafts (table activities)	64	19
Ceramics	9	3
Printing	5	2
	100	31

Variations for Hospital Types The larger plan is suitable for *general medical and surgical hospitals, psychiatric hospitals* and, with minor changes in equipment, for hospitals treating *physical disabilities*. Several units might be used for very large psychiatric hospitals. *Pediatric hospitals* are seldom as large as 500 beds; if so more personnel are needed.

Compiled by the Architectural and Engineering Branch, Division of Hospital and Medical Facilities, U.S. Public Health Service; August Hoenack, Branch Chief

CHECKLIST OF SPACES FOR A COMMUNITY MENTAL HEALTH CENTER

Facilities listed are those that may be required in the overall programs of mental health centers. They can be in one or several buildings on one or several sites, even under one or several cooperating ownerships. The list is for review by architects and administrators whenever new facilities are planned.

ADMINISTRATION

Office space for:

1. Director
2. Assistant director
3. Nursing director
4. Secretaries and typists
5. Business office

Ancillary spaces:

1. Record room
2. Staff lounge

3. Library
4. Conference room
5. Lobby and waiting
6. Toilets: public, personnel

DIAGNOSTIC & TREATMENT

Laboratory:

1. Office
2. Clinical
3. Pathology
4. Bacteriology
5. Washing and sterilizing

Suites:

1. Basal metabolism and electrocardiology
2. Morgue and autopsy
3. Dental
4. Eye, ear, nose and throat
5. Electroencephalography
6. Radiology

Physical therapy:

1. Electrotherapy
2. Hydrotherapy with exercise
3. Small gymnasium

Pharmacy department

Occupational therapy:

1. Space for small woodworking tools and benches for carpentry, metal work, leather work, printing, weaving, rug making, etc.
2. Office
3. Storage room

OUTPATIENT EXAMINATION AND TREATMENT

Office space for:

1. Psychiatrists
2. Psychologists
3. Social workers
4. Nurses
5. Health educators
6. Occupational therapists
7. Rehabilitation counselors
8. Recreation therapists
9. Clerical operators
10. Aides
11. Research analyst
12. Group therapy and conference

(Lobby, waiting space, and toilets may be combined with those in the administrative area.)

INPATIENT FACILITIES

Facilities may be required for the following types of patients grouped in accordance with the local program. (Separate spaces for male and female. Treatment and diagnosis spaces for each category.)

Patients' categories:

1. New admissions
2. Quiet ambulant
3. Disturbed
4. Alcoholic
5. Criminalistic
6. Day care
7. Night care
8. Children
 - a. Emotionally disturbed
 - b. Retarded

Each patient care unit:

1. Waiting space for visitors
2. Doctors' offices and examination rooms
3. Offices for psychologists, social workers, therapist or others as required
4. Nurses' station and toilet
5. Conference room
6. Therapy space
7. Day room(s)
8. Utility room
9. Pantry or nourishment preparation
10. Dining room
11. Washroom and toilets
12. Patients' lockers
13. Showers and bathrooms

14. Storage (for recreational and occupational therapy equipment)
15. Supply and linen storage
16. Janitors' closet
17. Stretcher alcove

Minimum room areas:

1. 80 sq ft per bed in alcoves and four-bed rooms
2. 100 sq ft in single rooms
3. 40 to 50 sq ft per patient in day rooms, preferably divided into one large and one small room

STERILIZING AND SUPPLY FACILITIES

(Sufficient to serve both outpatients and inpatients.)

SERVICE DEPARTMENT

Dietary facilities:

1. Main kitchen and bakery
2. Dietitians' office
3. Dishwashing room
4. Refrigerators
5. Garbage collecting and disposal facilities

Housekeeping facilities:

6. Can washing room
7. Day storage room
8. Staff dining room

Housekeeping facilities:

1. Laundry
2. Separate sorting room
3. Separate clean linen and sewing room
4. Housekeeper's office and storage (near linen storage)

Mechanical facilities:

1. Boiler room and pump room
2. Engineer's office
3. Shower and locker room

Maintenance shops:

Carpentry, painting, mechanical, repair rooms

Employees' facilities:

Locker, rest, toilet and shower rooms for various categories

Storage:

1. Medical records
2. General storage (a minimum 20 sq ft per bed to be concentrated in one area)

GENERAL HOSPITAL LABORATORY

Preliminary Planning

Locate the department as favorably as possible for the laboratory staff and the ambulant inpatients and outpatients. A space on the first floor near an elevator is preferable. Also, another determinant in locating the laboratory is the consideration for future expansion.

In determining the overall size of the laboratory, the first concern is the individual technical units. It is only after the size of these units has been established and an architectural layout has been developed to fit the program that the sum of the areas can accurately reflect the size of the laboratory department.

The square-foot-per-bed ratio is no longer considered a desirable guide in determining the size of a hospital department because of the wide variation of such factors as type and size of hospital, pattern of usage, growth of the community, and medical practice. Plans for the

Planning the Laboratory for the General Hospital, Public Health Service, Dept. of Health, Education, and Welfare, 1963.

HOSPITALS

Laboratory

laboratory area should be based on work volumes within specific ranges, such as 40,000-75,000 tests, or 75,000-120,000 tests. The key to this method is to estimate the work volume and its breakdown into work units for hospitals of different sizes.

The following is an outline of the procedure which may be used in estimating needed laboratory space, based on the number of tests performed, personnel, and equipment.

1. Break down the total volume of work into units, such as hematology, urinalysis, chemistry, as previously noted.

2. Determine the number of technologists required in each department. The data shown in Table 1 may be used as a basis for this determination.

3. Determine the necessary equipment and space for the number of technologists required.

For the purpose of developing guide material, the Architectural and Engineering Branch of the Division of Hospital and Medical Facilities collected data from 360 hospitals in addition to the data compiled by the Committee on Laboratory Planning of the College of American Pathologists. Tables 2, 3, 4, and 5 present these data.

Many laboratories show annual workload increases of about 10 percent, thus doubling the work volume in approximately nine years.

This annual increase should be considered during the planning stage of the laboratory. However, improved techniques and automation suggest that it may be possible for a greater volume of work to be done in the same work area size.

Laboratory Guide Plan

Plan A is a suggested plan for a hospital laboratory service with an estimated workload of 70,000 to 120,000 laboratory tests annually. For planning purposes, this laboratory is designed to serve a general hospital of 150 to 200 beds. The nontechnical staff would include one or more laboratory helpers in the glasswashing and sterilizing unit and a clerk-typist and secretary in the administrative unit. (See Fig. 1a.)

The laboratory services of a general hospital having this work volume would require work areas for six main technical units: hematology, blood bank, urinalysis, biochemistry, histology, and serology-bacteriology.

The block plan has been utilized here, as it provides a good functional relationship for all units. The pathologist's office in the center provides for easy supervision of the work stations; the hematology unit is near the waiting room; the bacteriology unit is at the end of the

laboratory, yet near the washing and sterilizing areas; and the histology unit is near the pathologist's office.

Other schemes similar to that shown in Plan D or a typical wing arrangement with a corridor down the center would also be satisfactory.

In the technical area of Plan A, the open plan arrangement (except for the histology and serology-bacteriology units) has several advantages over the "separate room for each unit" scheme for hospitals of this size. These advantages include: easier supervision; common use of such equipment as desks, refrigerators, and centrifuges; flexible use of personnel; and more available space since many doors and partitions are eliminated. If desired, partitions could be erected between each unit, as indicated on the plan for the histology and serology-bacteriology units.

Laboratory Module for Technical Area Maximum flexibility is desirable in the technical work areas of the laboratory department. In the plans, this has been achieved by using a module of approximately 10 by 20 ft, with a similar arrangement for each module. Each one consists of two standard laboratory workbenches 12 ft long, 30 in. deep, with a working surface or counter of about 23 in., and a reagent shelf. Knee spaces are indicated where needed for

TOTALS				3.21	6.12

personnel who perform tests from a sitting position. Drawers, cabinets, and shelves are provided below the work counter for daily equipment and supplies. This arrangement provides a 5-ft aisle between workbenches, which is considered optimum for movement within the working area. Equipment such as centrifuges, refrigerators, and desks, which may be used jointly by the personnel, is located opposite the units along the interior of the technical work area.

Technical Areas Hematology-Blood Bank Unit. A standard module is assigned to the hematology-blood bank unit. One half of this module is provided with a workbench for procedures such as hemoglobin tests, sedimentation rates, staining, and washing of pipettes (in Plan A, counter No. 7 on left side of unit). Knee space and storage cabinets are provided below the counter. In the other half of the module, a workbench 30 in. high, with three knee spaces, is provided for technologists who are seated during tests, such as those involving microscopic procedures.

The micro-hematocrit centrifuge, because of its noise and vibration when in use, is placed in the general technical area along the interior wall directly opposite the hematology unit. The other equipment needed by this work unit, such as a refrigerator, centrifuge, and recording desk, is located conveniently opposite the unit, where it is shared with the urinalysis and the chemistry units.

It is assumed that the laboratory will obtain blood for transfusions from other sources, and, therefore, needs only facilities for blood storage. A blood bank refrigerator is provided for this purpose in the examination and test room. Compatibility tests on the blood are done in the hematology unit. A hospital which operates a self-contained blood bank, that is, collects and does complete processing of all blood, should provide a separate bleeding room, processing laboratory, donors' recovery room, and an office available for preliminary physical examinations.

Urinalysis Unit. The urinalysis unit is assigned one half of a standard module, consisting of a workbench, 12 linear ft long and 30 in. high, and serves as the work area for the microscopic and chemical examinations. Five linear ft of the workbench and a knee space are provided for personnel performing the microscopic examinations; the remainder of the workbench is used for the chemical examinations. A sink located at one end of the workbench provides a continuous working surface for the technologists.

Biochemistry Unit. The biochemistry unit requires an area that occupies one and a half standard laboratory modules. The half module is shared with the urinalysis unit and is used for the necessary preliminary procedures that are done prior to the actual chemical analyses. A knee space is provided in this workbench for personnel who perform titrations and other procedures while seated. The adjoining module provides workbench area where a variety of chemical procedures may be performed and includes a fume hood for removal of vapors and gases.

The workbenches for the chemical procedures are about 36 in. high, with drawers and cabinets below. The reagent shelves are used to hold the chemicals needed during the procedures. Two utility sinks are provided, one in each chemistry work area. Apparatus used in this unit is cleaned by the personnel in the unit; test tubes, pipettes, and flasks are sent to the central glass-washing area nearby.

An instrument table 36 in. high is located

along the interior wall opposite this unit where chemical apparatus, such as colorimeter, flame photometer, spectrophotometer, and carbon dioxide gas apparatus are placed. Adjacent to the instrument table is an analytical balance on a vibration-free table or other type of support. By placing this apparatus away from the busy preparation and test procedure work areas, personnel can use the apparatus without interference from other procedures. It also lessens the possibility of damage to the equipment by the accidental spillage or splattering of chemical reagents.

A centrifuge, refrigerator, and desk are provided along the interior wall opposite the unit for the use of the personnel in this unit. The desk and refrigerator are shared with the urinalysis and the hematology units.

Histology Unit. The histology unit is assigned a standard module, separated from the other units by a partition to prevent odors from spreading to other areas. It is located near the pathologist's office since the medical technologist here works under his direction and supervision.

Along one half of the module, an area is utilized by the pathologist to examine surgical and autopsy specimens and to select the tissues for slide sections to be prepared by the technologist. An exhaust hood is provided over this section, as shown in the plan (No. 53), to draw off disagreeable odors from specimens and solutions. The remainder of the module is used for the processing and staining of tissues. Knee spaces are provided, one at each of the specialized work areas. The workbench is 30 in. high with a 22- or 23-in.-deep working area, cabinets and drawers below the counter, and a reagent shelf. Wall-hung cabinets are provided for additional storage. A utility sink is provided at the end of the workbench.

Serology-Bacteriology Unit. The serology and bacteriology work is combined in one standard laboratory module, where a half module is assigned to each unit. Culture media for use in bacteriology are prepared in the bacteriology work area and sent to the sterilizing unit for sterilization.

The workbenches are 30-in. high with a 22- or 23-in.-deep working area, and are provided with reagent shelves. A knee space is provided in each workbench since most of the procedures are done in a sitting position. A utility sink is provided for the personnel in both units, but the bacteriology unit also requires a sink for the staining of slides. A fume hood is provided to prevent the spread of possible infection to personnel when preparing specimens from suspect cases of tuberculosis, fungus, or virus diseases.

A centrifuge, refrigerator, and incubator are provided along the interior wall within the unit. A desk is also conveniently located for the use of the personnel.

This module is partitioned and separated from the other units by a door to reduce contamination of air and the hazard of infection to personnel in the other lab areas.

Administrative Area The administrative area is separated from the technical work areas so that the nonlaboratory personnel need not enter the technical areas. This is the central control and collection point for receiving specimens and is the reception area for the patients and the hospital staff who come to the laboratory.

Waiting Room. A waiting area, with conventional waiting room furnishings, is provided for the ambulant patients. In this area, a desk is provided for a clerk-typist. An intercommunication system between the technical areas of

the laboratory and the clerk-typist is recommended. This enables her to quickly notify the technical personnel when a patient arrives and also to transfer phone calls for information concerning a laboratory report.

The pathologist's secretary is also located in this area, near the pathologist's office. She takes dictation and handles all the pathologist's correspondence, surgical pathological reports, and autopsy protocols.

Venipuncture Cubicle. A venipuncture cubicle is provided where blood specimens are taken from the ambulant patients sent to the laboratory.

Specimen Toilet. A specimen toilet is provided in this area for the collection of urine and stool specimens; a pass window opens directly into the technical area near the urinalysis unit.

Basal Metabolism-Electrocardiography Room. A room is also located here for basal metabolism tests and electrocardiograms, and when necessary, to obtain blood from donors. A desk is provided in this room to permit handling of paper work. A lavatory is also provided.

Pathologist's Office. The pathologist's office is located so that he may have easy access to the technical areas of the laboratory, particularly the histology unit. This office is separated by a glass partition which permits the pathologist to observe the technical work areas. A draw curtain may be used when he desires privacy. Those who wish to consult the pathologist have access to his office through an entrance from the administrative area.

Auxiliary Service Areas The auxiliary service units are located adjacent to the administrative area and are easily accessible to the technical areas.

Glass Washing and Sterilizing Unit. The glass washing and sterilizing unit is close to the serology-bacteriology and the biochemistry units which will utilize such services more often than the other units. A separate door leads directly into the serology-bacteriology unit so that contaminated glassware need not be transported through other work areas.

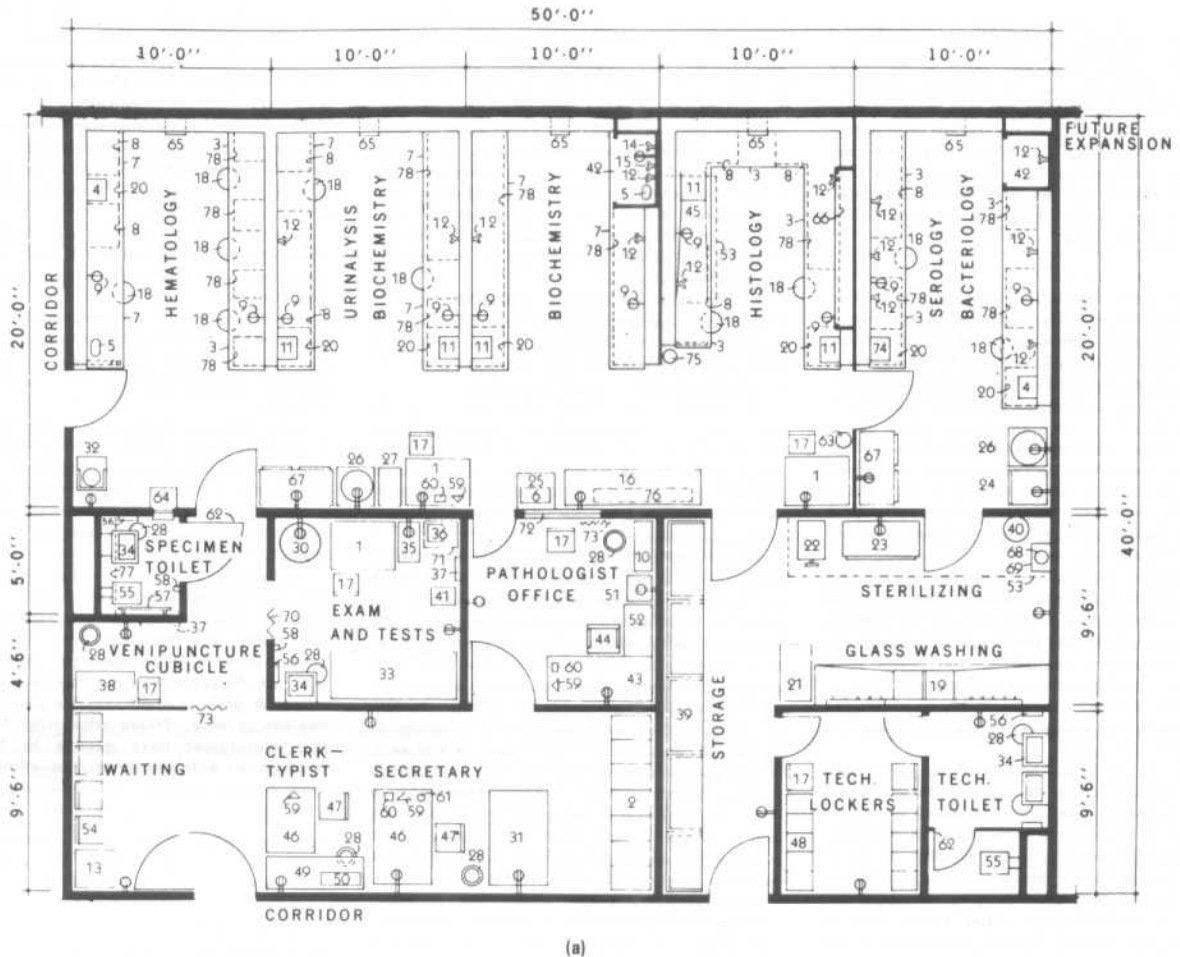

Within this unit are located a water still, pressure sterilizer, sterilizing oven, and pipette washer. Storage cabinets are also provided for stock items of glassware, chemicals, and reagents. A hood over the sterilizers and water still is used to exhaust the heat generated by the equipment. Utility carts used to transport dirty glassware from the various laboratory units to this area are parked in this unit.

Locker and Toilet Facilities. Separate locker and toilet facilities are provided within the laboratory department for the medical technologists. This convenience reduces the time personnel must be away from the work areas. Since most medical technologists are females, lockers have been provided for them in the department. However, where male technologists are employed, lockers should also be provided for them, either in the laboratory or in another location.

Optional Services. Clinical photography, medical illustration, and research facilities are not included in the plan because of their specialized requirements. If these services are to be part of the laboratory department, revision and expansion of the plan will be necessary.

Guide Plans for Smaller Hospital Laboratories

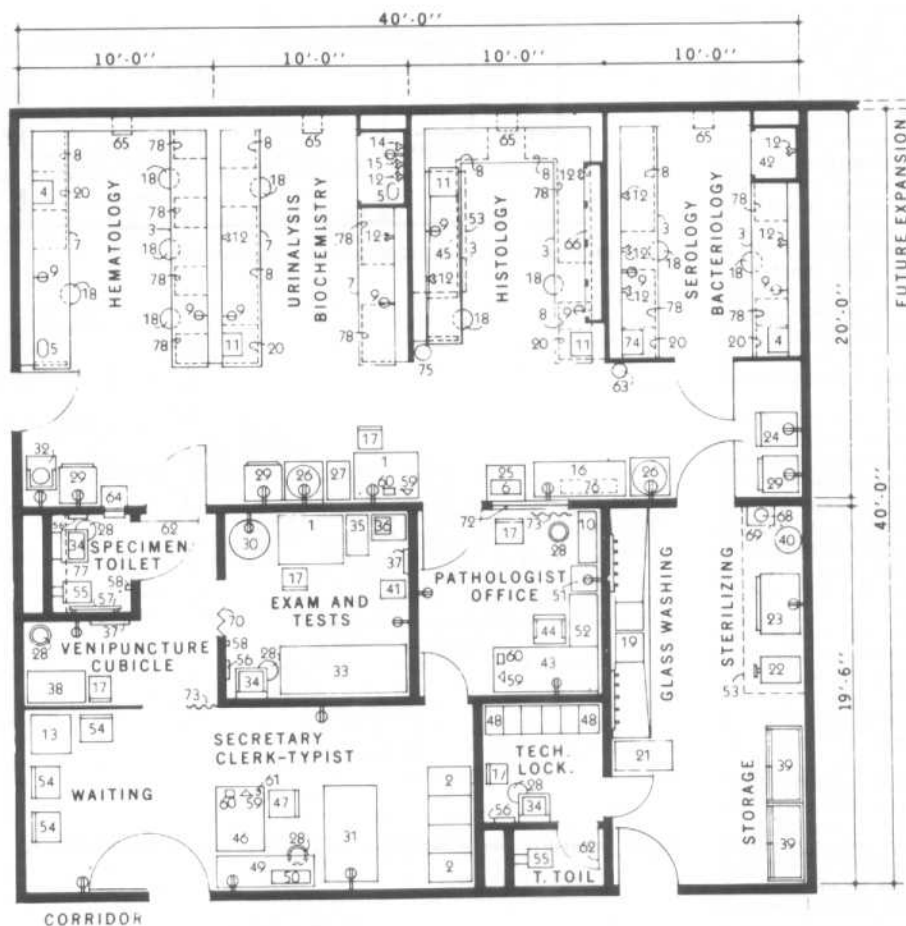

Plan B is a suggested guide for a general hospital laboratory service having an anticipated

HOSPITALS

Laboratory

annual workload of 40,000 to 75,000 tests. The estimated technical staff required to handle this workload is 4 to 7 medical technologists, based on the annual workload per technologist (Tables 1 and 5). The nontechnical staff would include one or more laboratory helpers in the glass washing and sterilizing unit and a secretary to handle the administrative work. This plan provides for a laboratory department having a full-time pathologist. It is assumed that a histology unit will be needed.

A laboratory service performing a yearly volume of 40,000 to 75,000 tests requires the same types of technical units as one that handles 70,000 to 120,000 laboratory tests. The space requirements for the technical work areas of the units are reduced, however, because the workload is less and fewer technologists are needed. (See Fig. 1b.)

Technical, Administrative, Auxiliary Areas. The plan provides four laboratory modules where the technical procedures performed include hematology, urinalysis, biochemistry, histology, and serology-bacteriology. Only the biochemistry unit is reduced in area because of less work and simpler procedures. The decreased work volume in the other units does not warrant further reduction of their work areas.

The principle of having equipment such as centrifuges, refrigerators, and recording desks close to the working unit which is to use them was followed as in Plan A.

Because of the decreased workload, the working area and the space for clerical personnel also are reduced.

The glass washing, sterilizing, storage space, and technicians' locker facilities also are reduced.

Plan D presents a design which might be used for a laboratory service in a small hospital. It allots the same areas for the technical, administrative, and auxiliary service units that Plan B provides, but the total square footage is less. However, more difficulty is encountered in providing as efficient a relationship between the administrative and auxiliary services and the technical laboratory units as in the plans for larger departments. (See Fig. 2.)

Plan C is a suggested plan for a general hospital laboratory service handling an annual workload of from 20,000 to 30,000 tests. The estimated technical staff required to handle this workload is 2 to 3 medical technologists, based on the workload per technologist and the annual volume of tests (Tables 1 and 2). The nontechnical staff would include one laboratory helper and a clerk-typist. (See Fig. 1c.)

The utilization of the standard laboratory module previously described permits even the small laboratory to be divided into technical, administrative, and auxiliary service work areas where the technologists may work in an area designed for the specific task.

Because of the decreased workload in a laboratory of this size, it is feasible to combine the hematology, bacteriology, and serology units by providing half a module for hematology and the other half for bacteriology and serology. A second module is provided for urinalysis and biochemistry, storage space, and refrigerator. Only the more common and simple laboratory procedures would be done in these units.

A glass washing and sterilizing area is provided directly opposite but apart from the technical work areas.

The administrative area provides a small waiting room where a clerk-typist receives patients and laboratory requests and specimens. In this area, a room is also provided for performing basal metabolism tests and

Fig. 2 Plan D alternate plan (40,000 to 75,000 tests annually).

Fig. 3 Perspective view of laboratory for general hospital of 150 to 200 beds.

Fig. 4 Diagram of piping behind laboratory workbenches.

electrocardiograms. This room also can be used for obtaining blood specimens from ambulant patients.

Utility Services

The utility service systems required in the operation of the laboratory include water, waste, gas, vacuum and compressed air. Because of the importance of these systems, the need for continuity of service, and the probability of future expansion, careful study is necessary in designing them for safety and efficiency.

Piping systems should not be exposed because they create housekeeping problems as dirt collectors and may be hazardous; many are noisy and unsightly. They should be located where they will be easily accessible for service

and repairs with a minimum of disruption of normal laboratory services. A sufficient number of valves, traps, and cleanout openings should be installed and should be located so as to permit maximum use of the facilities during repairs.

Laboratory benches are usually placed at right angles to and adjoining outside walls to effectively utilize space. This location of the benches simplifies, to some extent, the arrangement of the piping systems by installing vertical lines in the outside wall and mounting the horizontal piping on this wall. This arrangement is particularly advantageous for the waste vent stacks which must be carried vertically to the roof. Removable panels between the bench islands on the outside wall provide easy access to the main piping systems and sec-

tionalizing valves. Branch lines may be carried from the horizontal wall piping through the center of the island to serve the benches on both sides. (See Figs. 3 and 4.)

For safety purposes and to facilitate repairs, each individual piping system should be plainly identified by color, coding, or labeling. All waste piping should be of a noncorrosive material and should be discharged to a dilution pit or should be carried to a point in the piping system where the discharge will be diluted by waste from other areas.

Laboratory sinks should be made of noncorrosive material and should be designed for laboratory service. A waste grinder under the sink in the serology unit is highly desirable for disposal of clotted blood which may otherwise clog the drain.

LABOR-DELIVERY SUITE

Locating the Delivery Suite

Since the labor-delivery unit is basically self-sufficient, it may be located adjacent to the newborn nursery and maternity unit or elsewhere in the hospital; wherever possible, it should be located on the same floor. Transportation of mother and infant is reduced and maximum utilization of staff is obtained when all three units are together.

However, in large hospitals requiring more than one maternity nursing unit, another location may be required.

Planning the Labor-Delivery Unit in the General Hospital, Public Health Service, Department of Health, Education, and Welfare, 1964.

Functional Arrangement of the Delivery Suite

The delivery suite includes three areas of activity: labor, delivery, and recovery. Proper sequential arrangement of labor, delivery, and recovery areas within the labor-delivery unit facilitates patient care and aids the staff in carrying out proper medical techniques and practices. (See Fig. 1.)

Labor, delivery, and recovery rooms should be located and related for easy movement of patients from one area to another and for good patient observation. In large suites, locating service facilities on subsidiary corridors may help to reduce and control traffic.

From the standpoint of asepsis, location of delivery rooms and service facilities is critical. A location as remote as practicable from the entrance to the suite will reduce traffic, cause less air turbulence, and provide greater privacy for the patient.

Scrub-up areas should be adjacent to delivery rooms so that attending physicians can observe delivery room procedures and the condition of the patient.

A medical preparation facility serving labor and delivery areas should be convenient to both, accessible only to authorized personnel. This is usually located at the nurses' station or control area.

Storage for flammable anesthetics may not connect directly with anesthetizing areas.

A soiled holding room should be convenient for preparing the delivery room for a subsequent patient and for retaining soiled articles for disposal, processing, or return to central service.

Since the exact time of birth can seldom be determined, labor rooms should be close to delivery rooms but not so close that the two areas are intermixed or that patients in labor can overhear or view delivery room procedures.

A subsidiary corridor, if placed with a separate access to labor rooms, will permit the husband to visit in the labor room without passing through the main corridor and may also serve as a lounge area for ambulant patients and authorized visitors.

A recovery room should be located within the unit in an area: (1) adjacent to delivery rooms, or (2) near the main entrance to the unit. The determining factor may be the policy on permitting visitors to the recovery room. If no visitors are permitted, the first location has the advantage of immediate accessibility to delivery rooms and close proximity to the attending staff. The second location enables the husband to visit the patient without entering more restricted areas of the unit.

The location of the nurses' station will be determined to some extent by the size of the delivery suite and the nursing staff. A nurses' station for a unit of more than two delivery rooms should be placed near the entrance to serve as a control center for admitting and directing patients and performing other administration procedures without permitting these activities to interfere with other areas of the unit. If continuous attendance is difficult because of a small staff, the nurses' station may be located between labor and delivery areas so that nurses' travel to observe patients, keep charts, and participate in delivery room procedures is reduced.

Locker and toilet facilities for the obstetrical nursing staff and attending physicians should be included within the unit and arranged so that they will not enter clean areas in street clothes and will avoid exposure to contaminated areas after changing to obstetric garments. Where possible, entrances to these facilities from outside the unit are desirable.

The doctors' lounge and sleeping accommodations should be located within the unit

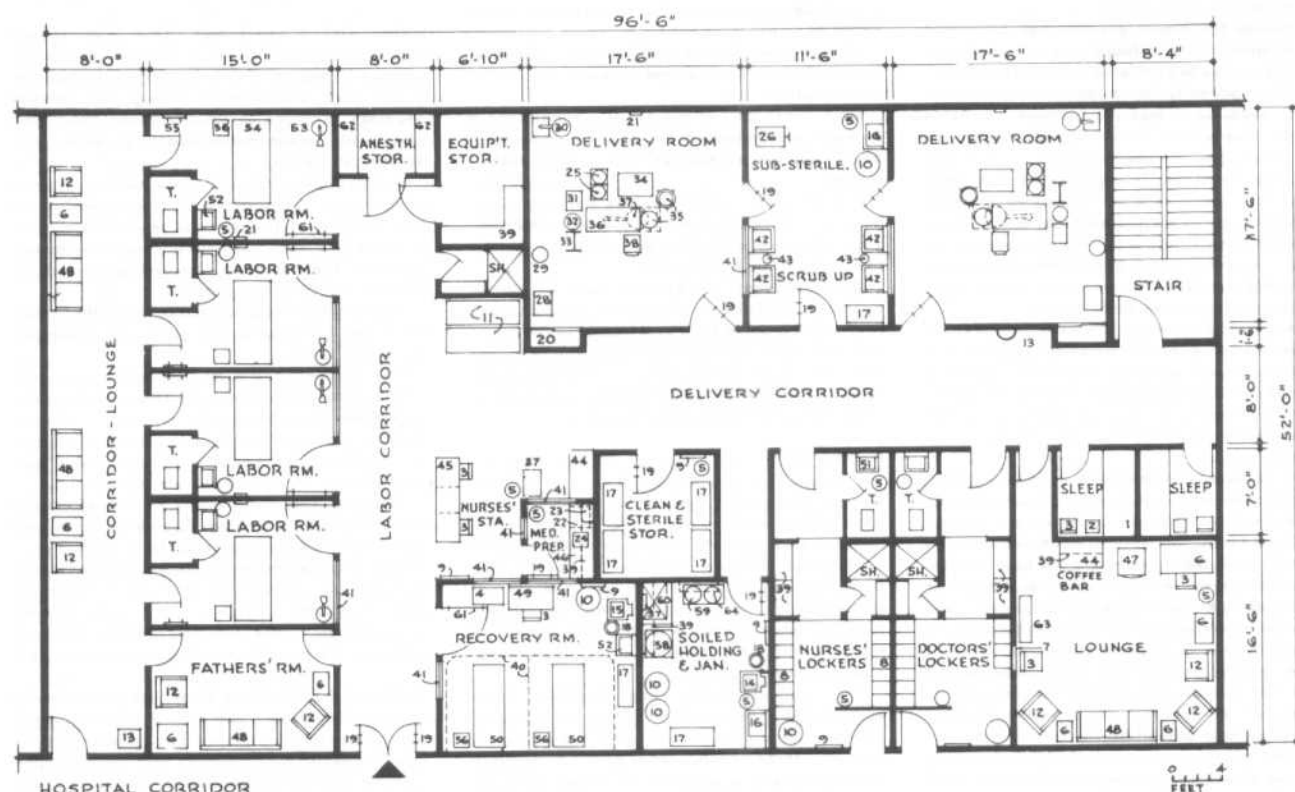

Fig. 1 Labor-delivery unit for approximately 1,500 births per year.

HOSPITALS

Labor-Delivery Suite

adjacent to their locker facilities so that the physicians may be immediately available for patients' needs. Even in the smallest hospitals, sleeping accommodations near the labor-delivery unit should be available to attending physicians.

Dictation facilities should be located in or near the doctors' lounge.

Admitting and Preparation Various methods are used to admit maternity patients:

1. Through the main hospital admitting desk and then either to a maternity nursing unit or to a labor room in the delivery unit.

2. Directly to labor rooms in the delivery suite.

3. In an admitting and preparation unit. An admitting and preparation unit is desirable in hospitals where a large daily patient load makes it necessary, after observation, to group patients: those to be returned home, those to be sent to the nursing unit, and those to be admitted to the labor-delivery unit.

If such a unit is provided, two locations are feasible: (1) adjoining the hospital admitting area, and (2) adjacent to but not a part of the delivery suite. The first location facilitates the admitting process and permits immediate patient examination, provided the obstetrical staff is available, and it also prevents patients not in labor or those destined for isolation from entering maternity nursing areas. The second location concentrates obstetrical staff activities in a single area of the hospital and allows immediate availability of the delivery suite in emergency cases.

Labor Rooms Labor rooms should provide maximum comfort and relaxation for the patient and should have facilities for examination, preparation, and observation. Unless an admitting and preparation unit outside the labor-delivery unit is available, the patient may be admitted directly to the labor room.

Although traditional practice has permitted two or more beds in labor rooms, single occupancy rooms are recommended. They eliminate the necessity for a patient preparation room, separate infectious patients, provide greater privacy, and if in accordance with hospital policy, permit the husband to visit the patient during labor. These rooms should have a minimum floor area of 100 sq ft. Multiple occupancy rooms should have not less than 80 sq ft per bed. If only one delivery room is required, one labor room should be arranged as an emergency delivery room and should have a minimum floor area of 180 sq ft.

A toilet and lavatory for each labor room provides privacy for the ambulant patient, and reduces bedpan services; however, patient's use of the toilet should be controlled. If individual toilet rooms are not provided, a single toilet room convenient to all labor rooms will suffice.

One shower and dressing cubicle is sufficient for the labor room area. If admittance, preparation, and shower facilities are located outside the unit, the labor area shower may be omitted. Each labor room should have a lavatory with gooseneck-type spout and foot- or wrist-operated controls, soap dispenser, and paper towel dispenser for handwashing by the patient, the nurse, and the physician.

The minimum width for labor room doors is 3 ft 8 in. However, to provide for the passage of beds or stretchers, 4 ft is recommended. Each labor bed should be furnished with oxygen and suction outlets and nurses' calling stations. Controls to provide adjustment of the level of general room lighting and the bed light are desirable. Air conditioning is recom-

mended. Music, piped into each labor room and controlled at the nurses' station, may be considered for the comfort of the patient. A cut-off in each room is required.

Delivery Room In designing and equipping the delivery room, every facility for the welfare and safety of the mother and the newborn child should be incorporated. Basic considerations include the immediate availability of equipment and supplies, built-in protection against anesthetic explosion, auxiliary electrical systems in case of power failure, an adequate air-conditioning system, and finishes that promote aseptic conditions.

Space allowance for equipment and for the staff to circulate freely is a primary factor in determining the size of a delivery room. A clear floor area approximately 17 ft 6 in. square is generally large enough.

The position of the anesthesiologist in the delivery room is determined by the arrangement of the backup table in the delivery room. This table is located in the cleanest area of the delivery room, away from all traffic and opposite the entrance to the sterilizer and scrubup areas. The feet of the patient are usually located nearest the backup table with the obstetrician at that end and the anesthesiologist at the opposite end. Since most anesthesiologists are right-handed, their equipment is located on the right, and it is desirable to place the door so that the anesthesiologist's equipment can be located where it need not be moved when the patient is brought in.

The view box should be located behind the anesthesiologist so that the circulating nurse may insert or remove films and the obstetrician may observe it without turning.

It is assumed that cesarean sections will be performed in the surgical suite.

A minimum ceiling height of 9 ft is required for an obstetrical light. Additional height is advantageous and may be required for some types of lighting fixtures.

Oxygen and vacuum wall outlets should be installed near the bassinets location for use in resuscitation.

Built-in cabinets in the delivery room should be kept to a minimum and used for storage of such supplies as sutures and special instruments.

The minimum width for the delivery room door is 3 ft 8 in.; however, 4 ft is recommended since patients will often be moved to the delivery room on a labor bed.

An emergency call system, foot- or elbow-operated, must have stations in each delivery room with a dome light and buzzer in the corridor over each delivery room door and in locker rooms, lounge, nurses' station, and other such areas. A nurses' intercom system must be provided between these same areas.

Recovery Room The recovery period, after delivery, is critical and may last from 1 to 3 hours. During this period the mother requires close observation and special care by the labor-delivery nursing staff. Some hospitals insist on continuous bedside attendance during this time. Various locations may be used for patients during the recovery period: a delivery room, a labor room, a bed in the maternity nursing unit, or a recovery room used exclusively for this purpose.

The recovery room has generally been accepted as a necessary facility in the delivery suite and should be considered for any hospital requiring three or more labor beds. A recovery room provides a location for recovering patients, frees the delivery or labor room for cleanup prior to occupancy by another patient,

concentrates patients in similar condition, and facilitates the special nursing care required.

In designing the recovery room, provision should be made for easy movement of stretchers or beds. If a number of patients will be cared for, a separate entrance and an exit may be advisable. Space should be provided for a nurse's desk, an instrument cart or table, a clean supply cart, a soiled linen hamper, and a waste receptacle. The nurse's desk should be large enough for a telephone, charts, a nurses' calling station, and forms and writing material. Cubicle curtains at each stretcher location should allow clearance for attending the patient from either side. Oxygen and suction outlets and a nurses' calling station should be installed at each stretcher position. Glass view panels between the room and the corridor facilitate observation.

Nurses' Station The nurses' station is the administrative and control center of the labor-delivery unit. Its size, complexity, and location will be determined by the extent of responsibilities charged to the obstetrical supervisor as well as by the size and staffing of the suite.

If patients are admitted directly to the labor-delivery unit, the nurses' station may be responsible for admitting procedures. Inventory and requisitioning of supplies may be handled at the nurses' station, although central service would assume this responsibility under a complement system.

If office records are extensive, file cabinets may be necessary. In large units, an office for the obstetrical supervisor may be required. A bulletin board should be provided for work schedules and hospital bulletins. A desk-height counter for the master station of the nurses' calling system, medical records, and a telephone may be adequate if the daily workload is small.

Doctors' Lockers and Lounge This area should contain a locker room, a toilet and shower room, a lounge, and sleeping accommodations. If the staff is not large enough to warrant separate facilities, a toilet-shower room and combined locker-lounge-sleeping room may serve staff needs.

In hospitals with only one delivery room, a minimum of 6 lockers is recommended; in those with more than one delivery room, a minimum of 5 lockers per delivery room is recommended. The minimum size recommended for a locker is 12 by 18 by 60 in.

Space should be provided in the locker room for a cart for clean scrub suits and a hamper for soiled linen.

The lounge should accommodate a couch, chairs, bookcase, magazine table, and a television set. A recessed film illuminator should also be provided. If dictation booths are not provided, a suitable desk and chair for this purpose should be included in the lounge.

Sleeping accommodations for the attending staff should be provided. For flexibility of use by either male or female doctors, it is preferable to provide single occupancy rooms for this purpose. In addition to the bed, furnishings should include chair and night table. If only a combined locker-lounge-sleeping room is required, the couch should open to make a bed.

Scrub-up and Substerilizing Areas Hand scrubbing by the obstetrician and nurse is an essential part of delivery technique. Facilities should be next to the delivery room so that the physician can see into the delivery room through a glass view-panel while scrubbing. On the plan shown in this publication the scrub-up and substeril-

izing areas are combined in one room. A door between this room and the delivery room is recommended. The area used for scrubbing should be deep enough so that persons scrubbing will not interfere with traffic and so that splashed water will not constitute a hazard.

If one scrub-up area is to be used for two delivery rooms, at least three scrub sinks should be provided.

The substerilizing area should contain a high-speed washer-sterilizer for emergency sterilization or for processing instruments.

Supply and Equipment Storage Supplies. The main factor in determining the space allocation for supply storage in the labor-delivery unit is the method and frequency of issuing supplies from central supply areas. Supplies include all items processed by the laundry and central sterile supply and those issued from central service. Excluded are pharmacy, anesthetic, or equipment items. All supplies should be kept in hospital central service and issued to the labor-delivery unit only after the required processing.

A more recent storage method uses the same carts on which supplies are delivered from storage of clean and sterile items. Supplies used only in the delivery room are packed on one cart and those for other use on other carts. Clean supply carts may also be assigned to doctors' and nurses' locker rooms for scrub clothes and towels. This method requires a clean supply room near the delivery rooms for carts containing clean or sterile items.

Equipment Storage. Equipment that is infrequently used, such as delivery table parts and duplicate equipment not in use, should be stored in an equipment storage room in the unit. This room should have shelves for small items and floor space for larger equipment.

Medications A medication preparation room or unit should be located near labor and delivery rooms for storage and preparation of drugs, including narcotics.

Medication preparation requires uninterrupted concentration by the nurse, and an enclosure or room with glass viewing panels is suggested for this function. A work counter with storage for syringes and accessories and a sink with gooseneck-type spout and foot or wrist controls for handwashing are recommended. If stepped shelves, sized for the smaller medicine bottles, are provided, the nurse can read labels quickly and arrange medicines in the order desired. A wall cabinet is suggested for bottles of solutions, and an eye-level locked cabinet for narcotics should be furnished. Since some medicines must be maintained below room temperature, a refrigerator is also required.

Anesthesia Facilities The anesthesiologist should be consulted early in the planning stage to determine design requirements for anesthesia facilities including what gases are to be piped; the number, size, and location of gas cylinders to be stored; and space required for cleaning and checking the anesthesia equipment.

Piping oxygen and vacuum to delivery rooms and other areas of the hospital is standard practice. In some hospitals, nitrous oxide is piped to the delivery room.

A room should be provided in the unit for storing gas cylinders. Flammable gases should be stored separately from oxygen and nitrous oxide, which may be stored in any location since there are no hazards involved. Small cylinders sized to fit the anesthesia apparatus may be stored in racks. Cans of volatile liquids

may be stored on shelves in the same storage area. Shelves should be provided for equipment such as pressure gauges. Large cylinders should be stored upright in racks. Space for a gas cylinder truck or carrier may be necessary. The primary purpose of storage for these gases and volatile liquids within the unit is to assure availability over weekends and at night when main hospital supply rooms may be closed. Storage space for a 48-hour supply of gas is considered maximum, and additional storage space on the unit is not desirable.

Instrument Processing The processing of instruments includes washing, preferably in a washer-sterilizer or by hand, disassembling where necessary, arranging for future use, and sterilizing.

One of several methods may be followed for instrument processing.

1. Soiled instruments are washed in the washer-sterilizer and sent to central sterile supply for processing. The plan shown is based on this assumption.

2. Soiled instruments are sent directly to central supply for processing. The washer-sterilizer is required for emergency sterilization.

3. Processing may take place in the unit under the direction of the obstetrical supervisor. In this case a workroom is required.

Soiled Holding Room All cleanup techniques including housekeeping are originated in this area, and soiled materials are placed here for disposal or return to central sterile supply for processing. This room will require a sink with drainboards for gross cleaning, a flushing rim sink for disposal of liquid wastes, a cart for storage of cleaning materials, carts and hampers to receive soiled articles, and a waste receptacle. Germicidal solutions and utensils used in cleaning should be stored here. If placentas are saved, a domestic-type deep freeze will be required.

RADIOISOTOPE FACILITY

Suggested Plans

Plans 1 and 2 in Fig. 1 show the relationship between the workload and facilities required.

Plan 1 Plan 1 is intended for a hospital anticipating limited isotope use in which the bulk of the workload will consist of relatively simple diagnostic tests such as thyroid uptake studies and occasional therapy using iodine-131 or phosphorus-32. Intracavitary therapy with colloidal suspensions of radioisotopes is not anticipated, nor are diagnostic procedures involving organ scanning. The one-room arrangement shown on Plan 1 may be sufficient in this case. (See Fig. 1a.)

A work counter (4) with built-in sink (5) and splashback is provided. Cabinets (3) and (1) located above and below the counter, respectively, provide storage space. Isotopes are stored on the work counter at area marked (A) behind lead bricks. Note that the area of the counter reserved for the isotopes is at maximum distance from the radiation detection instruments in the room, to minimize the possi-

bility of the radiation from the stored containers interfering with the use of these instruments. Also, the isotope area is on an outside wall and as far as possible from the corridor.

Two instruments are utilized in this plan, both of which, for the sake of economy, can be operated from the same scaler (10), mounted on a cart. However, in terms of flexibility, a separate scaler for each of the instruments might be preferable. The scintillation well counter (6) is located on the work counter, at the opposite end from the isotope storage area. The detector for thyroid uptake work (8) is used in conjunction with a patient examining table (7); both can be enclosed by a curtain (17) for patient privacy. A hook strip (18) is provided in this area for patient clothing.

The desk (12), chair (14), and filing cabinet (13) are for the use of the isotopes technician. It may be desirable to file records for patients, radiation monitoring, and isotope shipments in this area.

Because certain radioactive drugs require refrigeration, a small under-counter refrigerator might be added to this room. On the other hand, because the quantity of this heat-labile material commonly on hand in a limited isotope operation is small, the use of refrigerator space in another department, such as the clinical laboratory, might be feasible. If refrigerator space in another department is used, the radioactive material should be adequately labeled as to its radiation hazard and properly shielded before it leaves the isotope department. A third possibility would be the acquisition of one of the new miniature refrigerators, which are inexpensive, can be used on a counter top, and provide approximately 1 cu ft of interior space.

Plan 2 Plan 2 shows a two-room arrangement in which facilities are included for diagnostic scanning procedures and for occasional intracavitary therapy with radioactive phosphorus or gold, in addition to the general types of diagnostic procedures that would be done in the facilities shown in Plan 1. A larger overall isotope workload with more frequent therapy cases is also assumed. (See Fig. 1b.)

In the main room, two separate sinks are utilized. The clean sink (5) is used only for handling nonradioactive items, whereas the disposal sink (5a) is used to wash glassware contaminated with radioisotopes and to dispose of radioactive waste. To minimize contamination, the disposal sink should have an elbow or knee control.

Isotopes are stored, as in Plan 1, behind lead bricks on the work counter (4) at space marked (A). A refrigerator (15) is provided below the counter top conveniently nearby for the storage of heat-labile items, and space is also planned for a floor-type centrifuge (16) in this area.

The detector for thyroid uptake work (8) and the scintillation well counter (6) are operated in this plan from two separate scalers (10). Because of the larger volume of work, more work counter area is provided in this room than in Plan 1. The open floor space in the center of the room is larger than might be anticipated for a standard laboratory, to allow for the positioning of a patient stretcher, so that occasional intracavitary isotope therapy can be carried out here. The use of this room instead of the patient's room for intracavitary instillations has two advantages: the isotope area is more easily and safely decontaminated should spillage occur during the procedure; and movement of radioactive material through the hospital is minimized. Curtains hung from a ceiling track are used for privacy during these procedures.

The smaller room accommodates the scan-

ner (9), and the examining table (7) with which it is used. A hook strip (18) is affixed to one wall for patient clothing, and cabinets (1 and 3) are provided for storage of equipment and supplies. The sink (5) is for staff use prior to patient examination.

In the initial planning of the installation, consideration should be given to possible expansion of scanning facilities. Scanning procedures are time-consuming; as an overall guide, no more than four scans per day can be expected from each instrument. This will vary, of course, depending upon the diagnostic procedure performed. As the workload grows, a second scanning room may be required.

Hazards

There are two ways in which radioactive materials may be hazardous: First, some of their radiations present an external hazard to persons in their vicinity, as in the case of X-ray machines; second, when used in unsealed solution or powdered form, radioisotopes may be accidentally ingested or inhaled as a result of spillage or inexpert handling, thus becoming an internal hazard to personnel. Therefore, careful attention must be given to safe techniques and facilities to eliminate unintentional and potentially harmful radiation exposure to both personnel and patients when radioactive medicines are handled and administered.

Radiation Protection

In designing and constructing radioisotope facilities, the possibility of both external and internal hazards must be considered. To protect personnel against the radiation from externally located radioactive materials, *shielding*, usually made of lead, should be provided where necessary. In most instances, simple lead bricks arranged around radioisotope containers provide sufficient shielding. The most important factor in protection against the internal hazards of radioactive materials is the prevention of their ingestion or inhalation through safe operating techniques. The use of these techniques can be encouraged by providing facilities in the design of the radioisotope installation which lend themselves to safe working procedures. For example, smooth, nonporous counter tops and sinks should be provided to facilitate the cleanup of accidental spills.

Location

From the standpoint of safety and control, it is usually preferable that the hospital designate one department for radioisotope handling rather than allow all departments to administer radioisotopes to patients. In many hospitals, the radiology department is in charge of radioisotopes. If the radioisotope unit is located near its parent department, operations are facilitated because this allows for the efficient overlapping of staff duties and permits the sharing of examination and waiting rooms. Thus the location of the radioisotope unit will be dependent to some degree upon the location of the department that assumes responsibility for it.

Other factors will also influence location. For example, because many patients receiving diagnostic doses of radioisotopes will be handled on an outpatient basis, the radioisotope facility should provide convenient access from the street or elevators. Furthermore, locating the radioisotope facility at an exterior corner or corridor end permits the control of traffic.

OUTPATIENT ACTIVITY

Because physical medicine in the Outpatient Activity is used by both inpatients and outpatients, it is situated for the convenience and accessibility of both types of patients. Patients arriving at the Emergency Activity are evaluated (triage), and appropriate disposition is made of each case. The surgical suite is located close to the Emergency Activity to ensure the most rapid conveyance of a patient in a life-threatening situation. Cardiac arrest patients will receive immediate treatment by the code blue alert team within the Emergency Activity. After the crisis, the patient will be transferred to an adjoining intensive coronary care unit.

Since patients entering the Emergency Activity are frequently assigned elsewhere, close working relationships should exist with other areas of the hospital such as the surgical suite, intensive care units, and the main X-ray department.

Some additional working relationships between the Outpatient Activity and other hospital services are indicated in Fig. 1. Since these do not require immediate adjacency, they assume less importance on the relative scale of values established by either the overall planners or the designer.

Intradepartmental Relationships

Although the program of functions may delineate certain specific constraints and preferences as to disposition of the elements of an Outpatient Activity, the final outcome often is a compromise that represents the best acceptable solution to all parties concerned. (See Figs. 2 and 3.)

In one example, elements of the Outpatient Activity are arranged along the main circulation route. Since considerable traffic is expected, this corridor is 10 ft wide and forms the spine of the scheme. Branch corridors, each 8 ft wide, which separate other elements from each other, originate from the spine and provide access for people and goods to respective elements.

Since new patients do not know locations of the various clinics, some method must be devised to assist them. The architect can help by incorporating into the physical design a simple, easily understood system of signs. They might be either wall-mounted or incorporated into the floor surface, adding what can be an exciting physical design element to relieve the monotony of a long hospital corridor.

Becoming oriented within a modern hospital can be difficult even for a well person and especially confusing to a patient who is debilitated. Ability to control the internal environment has resulted in many windowless spaces in a hospital which are interconnected by a maze of corridors, especially in the diagnostic and treatment areas. To help resolve the orientation problem, specialty clinics (except pediatric) are grouped in one area. The pediatric clinic is in close proximity to the entrance to reduce travel distance for the mother carrying an infant.

The control and administration or business office should be the primary contact between the patient and the institution. This is the point of origin of the service where disposition is made as to what is appropriate for the patient.

The two categories of outpatients are: (a) new

patients for whom admission records and other documentation must be prepared and (b) repeat patients whose documentation is on file.

Administration

All patients enter the facility through a vestibule which provides protection from inclement weather. They are greeted by a control officer in the business office who has an overview of all incoming people and orients patients to processing. (See Fig. 12.)

Admitting On the first visit, the patient is directed to one of the admitting interview cubicles which form an integral part of the business office. On completion of the admitting procedure, a clerk summons a messenger whose station, which should be large enough to store wheelchairs, is adjacent and connected to the business office. He [she] escorts the patient directly to the intake screening center or, if it is fully occupied, to the public waiting area.

The repeat patient who has an appointment to a specific clinic stops at the check-in station where he [she] receives instruction. He [she] may go directly to the clinic or wait in the public waiting space until notified by the control officer. (The business office is responsible for checking patients in and out and for collecting fees, if applicable.)

Despite rigorous efforts and best intentions in establishing schedules and appointments, delays due to unforeseen circumstances will occur. Hence, patients and family members must be afforded an appropriate waiting place also needed by patients awaiting prescriptions issued from the pharmacy dispensary. This suggests that the dispensary be directly accessible from the public waiting area and that visual signals be installed near the issue windows indicating when the prescription is ready.

All patients, upon completing their visit, report to the check-out station where they are issued instructions for a repeat visit, if necessary. The architectural design accommodates these requirements.

INTERDEPARTMENTAL
RELATIONSHIP SCHEME

Guidelines to Functional Programming, Equipping, and Designing Hospital Outpatient & Emergency Activities, DHEW Publication No. (HRA) 77-4002, U.S. Department of Health, Education, and Welfare, Washington, D.C., 1977.

Fig. 3.

Fig. 2.

HOSPITALS

Outpatient Activity

Medical Record Unit The medical record room is strategically placed near the business office and adjacent to the examination-treatment center for easy access. It is served by a pneumatic tube station and messenger service.

Medical Social Service Center An important outpatient service is health education and follow-up care that may extend into the patient's home. The center provides a base of operations for medical social service for evaluation and future follow-up, if indicated. The follow-up extends patient care into home and community.

A large multipurpose room is provided for large-group health education. Conveniently placed near the entrance, it can be used when the rest of the Outpatient Activity is closed.

Home Health and Public Health Nursing Center Adjacent and interconnected to medical social service is the home health and public health nursing center. Both have reception and patient sub-waiting areas.

Specialty Clinics

Adjacent to both the Administration and the Examination and Treatment Center are the clinics designed and equipped for special procedures. (See Figs. 2 and 3; see also Fig. 11.)

All new patients pass through the intake screening center where medical evaluation and disposition are made regarding subsequent medical treatment. Medical history and documentation are initiated and routine laboratory testing performed. Therefore, provision must be made for separate specimen collection spaces for men and women, a routine testing laboratory, and a sub-waiting area with a registered nurse in attendance. Appropriate spaces and fixtures are provided for handicapped persons.

The laboratory and x-ray unit will serve the Outpatient and Emergency Activities. The laboratory, with pass-through windows for specimens, will use pneumatic tubes for forwarding specimens to the main hospital's laboratory. An x-ray unit

for diagnostic purposes should be large enough to accommodate stretcher patients.

Patients requiring extensive diagnostic tests can be referred to the main hospital's radiology department and pathological and pulmonary function laboratories.

While the EEG and ECG clinics are located within the Outpatient Activity, they serve the entire hospital.

Examination-Treatment Center

A large portion of outpatient workload will be handled in the examination-treatment center rather than in the specialty clinics. Hence, a waiting room with public conveniences is provided. The layout of the center, Fig. 4, was called for by the program of functions which designates three work components herein called clusters. Each cluster consisting of ten examination-treatment rooms surrounds its own central utility work space designated as a personnel corridor. (See Fig. 5.) Other configurations may be equally appropriate.

In the first phase, 30 examination-treatment rooms are provided. Future expansion to add 30 rooms must, of necessity, be linear along the utility work space. This corridor must be limited in length to approximately 100 ft because experience shows greater distance to be undesirable. All the examination-treatment rooms are accessible from a system of patients' corridors stemming from the waiting room. In addition, personnel corridors are accessible from the outside corridor.

With the exception of general and special surgery, proctology, and urology, all examination rooms are similar in size and design.

No special provision is made for patient disrobing since either a ceiling track curtain or a folding screen may be used. It is assumed that the physician examines one patient while another undresses in an adjacent examination room. In most cases, allocation of two or more examination rooms per physician allows economic use of his [her] time.

The following scheme will apply throughout:

EXAMINATION-TREATMENT CENTER
INDIVIDUAL CLUSTER SCHEME

Fig. 5.

- Each examination room will have not less than 80 net sq ft of usable floor area. Rooms also used for treatment shall not have less than 120 net sq ft of usable floor space.
- Examination or treatment tables are to be accessible on three sides allowing for working space of not less than 30 in clear on each side.
- Handwashing facilities for attending staff must be provided.

The clinics of the center are grouped by similarities of medical specialties. All are identically equipped except those listed below which have individual needs:

General and special surgery	Metabolic
Proctology	Neurology
Urology	Allergy-
Diabetic	Dermatology
	Cardiovascular

See also Fig. 9, for specific equipment recommendations.

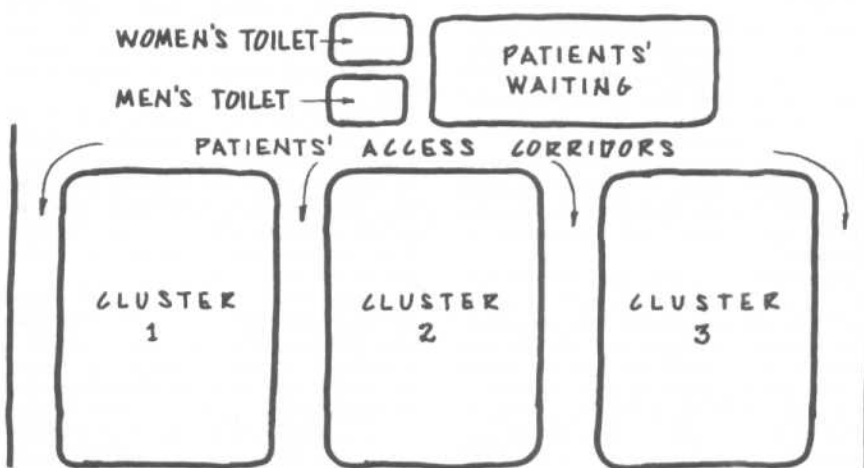

Physical Medicine and Rehabilitation

This unit which incorporates physical and occupational therapy, although an integral part of outpatient service, is a separate entity. Serving both outpatients and inpatients, the unit's location may cause somewhat of a dilemma. In the scheme illustrated in the example (Fig. 6), it is clearly identifiable and its functions are administered by unit personnel.

The services provided reflect the functional programming requirements rather than what this department should or should not be. Other programs could include a prosthesis workshop, fitting rooms, and multidiscipline conference rooms, among others. That every individual situation or program requires an individual planning solution to meet specific local needs cannot be overemphasized.

Although an element of outpatient service, Physical Medicine and Rehabilitation (PM&R) also serves the inpatient hospital population. Accessibility from outside as well as from inside the hospital without impeding outpatient services requires the designer's special consideration.

PM&R consists of two principal elements: physical therapy and occupational therapy. While these activities are subject to interpretation, the elements and equipment provided are expected to constitute a comprehensive approach to the normally recognized concept of an Occupational Therapy Department. The two departments are

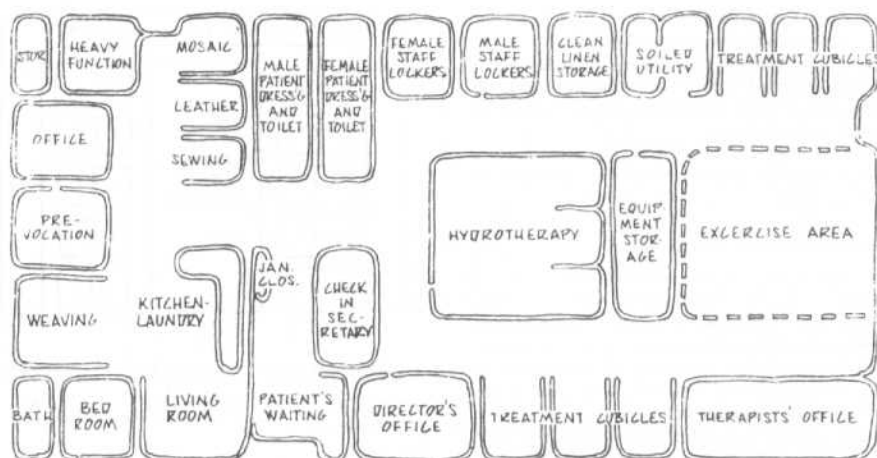

EXAMINATION-TREATMENT CENTER
RELATIONSHIP SCHEME

Fig. 4.

HOSPITALS

Outpatient Activity

PHYSICAL MEDICINE AND REHABILITATION
RELATIONSHIP SCHEME

Fig. 6

adjacent but separate with their own staffs; administration and control may be shared. Figure 6 illustrates the relationships between individual spaces within the departments and reasons for them as understood by an architect.

PM&R is under the physiatrist-director whose office is accessible from the outside corridor, the secretary's office, and from within the department, thus facilitating overall supervisory duties.

Special attention is given to the fact that many patients are physically incapacitated and use prosthetic appliances or wheelchairs. Some inpatients may be brought in on stretchers. Therefore, corridors are a minimum of 6 ft wide. Wheelchair patients are provided special plumbing fixtures, drinking fountains, and large cubicles for dressing and undressing.

Corridor wall handrails are controversial. Those against maintain that patients should learn to be independent and not have handrails. Those for believe that the weak, uncertain patient needs assistance which he [she] can ignore later. Because patients in PM&R should be under continuous supervision or attended by staff, the decision must be made by the institution. To be a useful aid for handicapped persons, the handrail must be designed to meet the users' anthropometric requirements. It must be substantial, offset from the wall, and well secured to prevent anchorage failure and possible injury.

Opinions differ regarding provision of a tank in hydrotherapy for total immersion of the patient's body. Some authorities recommend elimination of the tank. Others advocate provision of a swimming pool. Obviously, the latter cost implications are so great that the issue can only be resolved by each individual program.

Hydrotherapy produces a large volume of soiled wet linen which is often overlooked or given insufficient recognition. Adequate provision should be made either for collecting, temporarily holding, and transporting this linen to the hospital laundry or for processing in the physical medicine department.

The spaces indicated in Fig. 6 accommodate the equipment recommended (see Fig. 10). The physical therapy entity is based on the racetrack corridor principle, facilitating movement of people and equipment from one part of the facility to

another. Wet activities such as hydrotherapy are purposefully placed in an enclosed room. The exercise area is placed apart from other activities to help preserve patients' dignity and alleviate their apprehension and self-consciousness as they try to regain their previous mobility or agility.

The Occupational Therapy Department shares some facilities with the physical therapy entity. These are control-administration and patients' dressing and toilet facilities. Unless the function of a particular space dictated that it be enclosed, the PM&R facility should be as open as possible which facilitates needed visual supervision. For example, windows are provided in room 27 [Fig. 10]—the heavy function activities area—to enclose noise and airborne particles, yet allow visual observation.

Automated Multiphasic Health Testing Unit

Multiphasic health testing or multiphasic screening is a system which involves collecting, organizing, storing, and presenting medical data for the purpose of detecting body malfunctions before symptoms become obvious. Thus, the physician is enabled to initiate early treatment.

This type of service involving multiple tests is in a developing stage. The example presented in this publication, therefore, should be evaluated carefully against local clinical and diagnostic requirements.

The tests are similar to but more extensive than those usually given by an internist or a general practitioner during a complete physical examination. Multiphasic testing differs in that it is systematized and automated with maximum reliance on electronic recording instruments; the tests, in most cases, can be administered by a technician rather than by a medical practitioner. An electronic technician must be available to ensure that the electronic and mechanical instruments are functioning properly and recording the results. Operating personnel must understand how the instrumentation works. Only with the use of automated methods are testing programs designed for large population groups economically feasible.

Automated instrument packages are of three types: (1) instruments that either come in contact physically with the patient or scan and record

a function, such as vision; (2) laboratory test instruments used on samples taken from the patient; and (3) interpretive instruments or computer hardware.

Tests should be grouped so that they will be carried out expeditiously. Careful grouping minimizes the feeling by patients that they are on an assembly line. However, the more tests given at one component, the greater the operator skill required. Furthermore, if it takes twice as long to go through a component, the number of parallel stations must be doubled to maintain the patient flow rate. Thus, test equipment must be duplicated.

Generating the individual medical report is the primary function of multiphasic screening. The report will convey to the physician all information gathered during the examinations. This is the rationale for using electronic data processing for large volume operations in the storage, analysis, and retrieval of test information. The ultimate goal is to have all results automatically fed into a computer so that immediately after the testing is completed all subsequent diagnostic procedures may be scheduled. Many instruments used do not have this capability and many tests require manual processing or visual observation reporting.

Data processing should, therefore, be incorporated only after careful analysis and justification. Use of semiautomated procedures frequently must be considered. Card forms may be designed that can accept pencil entry of all clinical data. A mark-sense document reader may serve as one type of data entry terminal to the computer. Of course, data entry keyboards may be used for manual input of data as well as automated instrument input of test results.

The Automated Multiphasic Health Testing Unit described in the pro forma example (Fig. 8) is located near the entrance so it may be used and operated separately from the other clinics and on a different time schedule, if desired, or even omitted. It is incorporated in the Outpatient Activity to illustrate one aspect of preventive medicine.

A self-contained entity having its own supportive staff and resources capable of acting independently, the unit is related organizationally to the overall outpatient service. Patient flow through the facility should be expeditious with no backtracking. The clinic is oversized in anticipation of future increases in the number of patients.

The health evaluation procedures and tests are carried out at test stations or rooms; they follow a definite established sequence as shown in the pro forma example. The sequence and timing have special importance for medical reasons. An example is the time interval that must elapse between administration of drops for pupil dilation and the eye examination.

Opinions vary as to the time interval required for certain tests. Therefore, the tests which take place between critical events must be fitted in according to individual situations encountered. No universal rule can be established regarding the number of testing stations or their sequence.

Figure 7 illustrates the sequence of events. Patients arrive at the reception registration area, A-1 (in Fig. 8), which is large enough to accommodate several people. Following admitting procedures, they take glucose in space A-2 and proceed to A-3 to execute their medical history. Afterwards they go to their respective locker rooms (A-5 for women and A-13 for men) and change into a hospital gown, depositing street clothing in lockable lockers. The next station is A-8 where tests are performed for audio and visual acuity.

HOSPITALS

Outpatient Activity

Fig. 7. Automated multiphasic health-testing sequence.

The next stop is A-10, general procedures room, which also accommodates two ECG testing stations. The next stations are A-14 for chest x-ray and A-15 for spirometry. Eye drops are also administered at A-15. A subwaiting area, A-17, is an alcove where patients may wait when delays occur between tests without obstructing corridor traffic. The next stations are dental examination, A-16; achilleometry, A-18; retinal photography, A-22, where eye examinations, including tonometry, are performed. Sufficient time has elapsed between administration of the eye drops at A-15 for the fundus photo to be performed.

The next station (either A-23 or A-25) is where proctoscopy and sigmoidoscopy (i.e., endoscopic) examinations are performed. Both rooms have toilet facilities. A-24 accommodates venipuncture where blood samples are drawn. (The elapse of a prescribed time period is essential from the time of glucose ingestion in A-2 to venipuncture in A-24. This pro forma example requires 2 hours for this procedure, with a ± 15 -minute deviation.)

After A-24, the flow of patients divides. Men, after providing specimens, go to locker room A-13 to don street clothing. A specimen toilet is provided for each sex. Each toilet is provided with a pass-through window to room A-9 which is a laboratory pick-up station. Specimens are collected from patients and transferred by messenger to the main hospital laboratory for processing. Women, after leaving A-24, proceed to the Papanicolaou smear examination room, A-27, through temperature equilization rooms, A-29 or A-30, for the thermography examination in A-31. After completion of these procedures, they give their specimens at A-7, and go to the locker room, A-5, to dress. All patients are required to fill out the psychological questionnaire in A-28. Round-table discussions on health education are conducted by staff in A-33. The screening process ends in A-1 where the receptionist/registrar checks out the patient.

The facility has a storeroom, A-12, for general and medical supplies. A lounge room, A-19, and record storage room, A-32, are provided for the automated multiphasic health testing unit staff; staff toilets for both sexes, A-20 and A-21, are also provided. There is a director's office, A-4, and chief nurse's office, A-6, and a janitor's closet, A-26. All designated spaces or rooms are provided with the necessary furniture and equipment to carry out medical and administrative tasks.

HOSPITALS

Emergency Activity

EMERGENCY ACTIVITY

In planning the Emergency Activity, particular attention must be paid to movements of people (patients and staff) and material (equipment and supplies). The first priority, of course, must be the movement of those patients who require immediate or urgent medical attention and the responding members of the medical staff. The time factor in terms of minutes can make the difference between life and death. All necessary equipment and lifesaving apparatus must be located in designated spaces so as not to impede the movement of staff yet be readily accessible when needed.

According to the pro forma example (Fig. 1), the Emergency Activity is intended to be a casualty center offering services 24 hours per day. Medical, surgical, and nursing services as well as first aid are provided. A main premise is that dignity of patients and their families will be respected and protected at all times. During the early years, about 35,000 visits annually are expected which will rise to 50,000 in about ten years. Supportive services such as laboratory, diagnostic x-ray, electrocardiographic and pulmonary function facilities will be located at the boundary between the Emergency and Outpatient Activities, assuring easy access to both.

The Emergency Activity should be located on the ground floor to ensure easy access for patients arriving by ambulance or auto. A separate entry for walk-in patients is required. These entrances, which are separate from the Outpatient Activity, must be easily identifiable, protected from inclement weather, and accessible to handicapped patients. The emergency facility also must be easily accessible from the hospital to patients and to the house staff performing their routine duties or being summoned for consultation or emergency action.

Intradepartmental Relationships

Since they share some supportive facilities, the emergency and outpatient facilities are adjacent to each other. Good planning practice requires that the Emergency Activity be easily accessible to the hospital's surgical suite, coronary intensive care unit, and the primary radiological facilities. (See Fig. 1.)

The relationships within any Emergency Activity may be arranged according to individual preference and needs. The following should be considered for any complete emergency activity:

Public Sector Areas

- Entrance for patients arriving by ambulance, other modes of transportation, or conveyances
- Entrance for walk-in patients
- Control station
- Public waiting space with appropriate public amenities

Treatment Facilities

- Patients' observation room
- Treatment cubicles
- Examination rooms
- Cast room
- Critical care rooms

An Emergency Activity may also include a patient's security room and areas providing supportive services and staff accommodations.

Figure 2 is a graphic interpretation showing space relationships. As stated earlier, the first priority is the movement of patients requiring immediate medical attention. The patient brought by ambulance is conveyed on the ambulance stretcher directly to either a treatment cubicle or to a critical care room. An alcove holds stretchers and wheelchairs for patients arriving by vehicles. If the situation requires use of an operating room, the patient is admitted administratively to the Emergency Activity and conveyed through the door by the critical care room to the surgical suite.

Public Sector Area The admitting procedure is accomplished at the control center either by a family member or another individual accompanying the patient. The walk-in patient enters through the vestibule left of the control center and registers for admission at the center. Afterwards he may be asked to wait until called in public waiting space with his escort or family member. Admitting personnel exercise their medical judgments in each case as to the degree of medical urgency

and, if necessary, request a physician to make a disposition. In some cases, the patient may be referred to the adjacent Outpatient Activity.

The control center is placed strategically to provide visual control of all incoming traffic and observation of the public waiting area so personnel may be aware of any medical emergency that may arise there. Near the entrance, the control center has an external window so an approaching ambulance may be observed. Vestibules to eliminate drafts at the entrances provide a certain amount of comfort for control center personnel. The center could be enclosed with a glazed partition but, although transparent, it is perceived by patients as a physical barrier. The counter at the control center also serves as a barrier against cold drafts. It must be emphasized that the response the patient receives at admission leaves lasting impressions. Thus, special attention should be given to provide an atmosphere of professional competency.

The radio room, incorporated with the control center, serves as a communication link with ambulance crews or rescue units in the community. The

Guidelines to Functional Programming, Equipping, and Designing Hospital Outpatient & Emergency Activities, DHEW Publication No. (HRA) 77-4002, U.S. Department of Health, Education, and Welfare, Washington, D.C., 1977.

HOSPITALS

Emergency Activity; EDP Unit

police room may also be used by reporters and attorneys. Immediate members of the family may retire to the family room pending the outcome of medical intervention involving a life-threatening situation of a patient; here, doctors and clergymen may converse with the family.

Waiting in an Emergency Activity is a particularly difficult time for every patient since each perceives his medical urgency as unique. A state of anxiety predominates. The environment, obviously, should not only cater to physical needs and comfort but should also instill a feeling of confidence and relieve anxiety or fear.

Toilets for both sexes adequately screened from the public view, telephones ensuring privacy, vending machines with beverages or snacks, comfortable seating arrangements (not benches) all contribute to physical comfort. The general design of the waiting space (including color, texture, decor, acoustical control) all contribute to the welfare of waiting patients. The public waiting area should be screened visually from incoming ambulances discharging patients. A daylight window to the outside is often desirable but care should be taken to avoid location that will focus attention of the patients on ambulance arrivals.

Treatment Facilities Patients are treated in spaces surrounding the nursing station, the hub of all activities. This station is backed up by the medical preparation room and the office of the chief nurse who supervises all operations. Therefore, a glazed partition is provided which ensures acoustical privacy and affords visual control.

Staff amenities include toilets, lounge, and locker room for female staff. Lounge and sleeping accommodations are provided for three full-time physicians and resident medical staff who often work long hours and, although not continuously, are on call.

The chief physician's office is located in close proximity to that of the chief nurse since they often communicate face to face. Emergency equipment, to be readily accessible in case of urgent need, is deliberately placed in an alcove in front of the nursing station.

The patient's security room, with an unbreakable view window for observation, is placed close to the nursing station. Curtains may be installed outside the room, if necessary, to eliminate a view from the room itself. The door to the room and to its toilet must open outward to prevent the patient from locking himself [herself] in. To prevent self-injury, the room should be devoid of any sharp-edged appurtenances, and the light fixture, preferably tamperproof, should be flush with mounting surface. Surfaces should be smooth without any crevices with coved wall bases to facilitate easy cleaning in case of gross soiling by a disturbed patient.

It is important to emphasize that this is not a prison cell or a dry-up tank for an alcoholic. The patient confined in this security room is there for medical treatment although he may be under police control or may be mentally unstable. Physical design that provides a pleasant atmosphere is of paramount significance.

Treatment cubicles have curtains for privacy, if necessary, and are equipped to handle examinations and minor treatments. More severe injuries are treated in critical care rooms which are of two sizes. For a coronary patient, the emergency team may consist of a number of specialists using numerous kinds of portable equipment; therefore, larger space is required to accommodate both. Conductive flooring must be provided if explosive anesthetic gases are used and all

safety regulations must be observed. Each critical care room is provided with a scrub sink. Special attention should be given to the scrub sink area because of the hazards of infection and a slippery floor.

The cast room, used for closed reduction of fractures, is equipped similarly to a treatment cubicle with the addition of a plaster sink and trap. All supplies, splints, and fracture frames are kept in the room. The door must allow passage of a patient on a stretcher who, after treatment, may be immobilized by means of orthopedic accessories and attachments to the stretcher.

The patient's observation room must be in full view of the nursing station. Privacy between patients may be achieved by a cubicle curtain. Toilets for both sexes are provided. Nurses' work counters are at each end of the room.

The entire Emergency Activity is easily accessible from the hospital and the x-ray and laboratory facilities which, located between the two activities, are shared with the Outpatient Activity.

Fig. 1 Shared terminal service electronic data processing unit.

Data Entry and Transmission Room (Shared Terminal Service System)

Function This area accommodates equipment and personnel necessary for encoding source data onto computer compatible magnetic tape, transmitting the encoded data to outside computer facilities for processing, and receiving the processed data in conventional printed copy form.

Occupancy Two tape entry operators, one tape transmission operator, and occasionally the programmer-analyst.

E.D.P. Secretarial Office

Function This area provides facilities for reception and secretarial service to the E.D.P. director and systems analyst(s).

Occupancy Secretary and waiting for three visitors.

Adjacent Areas E.D.P. director's office, systems analyst's office(s), and administrative corridor.

Systems Analyst's Office(s)

Function Each subject office area or work station (one is assumed for the shared terminal service E.D.P. unit and two for the medium system E.D.P. unit) provides for a systems analyst who is responsible for planning, scheduling, and coordinating activities required to develop systems for processing data and obtaining solutions to complex problems. He [she] is concerned with developing

methods for computer usage in the various areas of hospital operation, such as financial management, material management, admitting, medical records, clinical pathology, outpatient service, and others. He [she] works with the management engineering unit personnel to improve operating methods and systems which provide for more efficient interdepartmental operation.

After determining the exact nature of the data processing problem, he [she] defines, analyzes, and structures it in a logical manner so that a system to solve the problem and obtain the desired results can be developed. He [she] obtains all the data needed and defines exactly the way it is to be processed. He [she] prepares charts, tables, and diagrams and describes the processing system and the steps necessary to make it operate. He [she] may recommend the type of equipment to be used, prepare instructions for programmers, and interpret final results and translate them into terms understandable to management.

When working with systems already in use, the systems analyst is also concerned with improving and adapting the system to handle additional or different types of data.

In 500-bed hospitals, one of the senior systems analysts is designated "Chief."

Occupancy Systems analyst and seating for three visitors in each office.

Adjacent Areas Shared terminal service system: E.D.P. secretarial office, E.D.P. director's office, and data entry and transmission room.

Medium system: E.D.P. secretarial office, E.D.P. director's office, and E.D.P. programming area. Convenient communication with the E.D.P. supervisor's office and E.D.P. machine room essential.

E.D.P. Programmer's Office(s)

Function This area provides for the E.D.P. programmers who prepare step-by-step instructions that tell the computer exactly what to do. Three programmers, each with a separate work office or cubicle within this area, are assumed for the medium system E.D.P. unit.

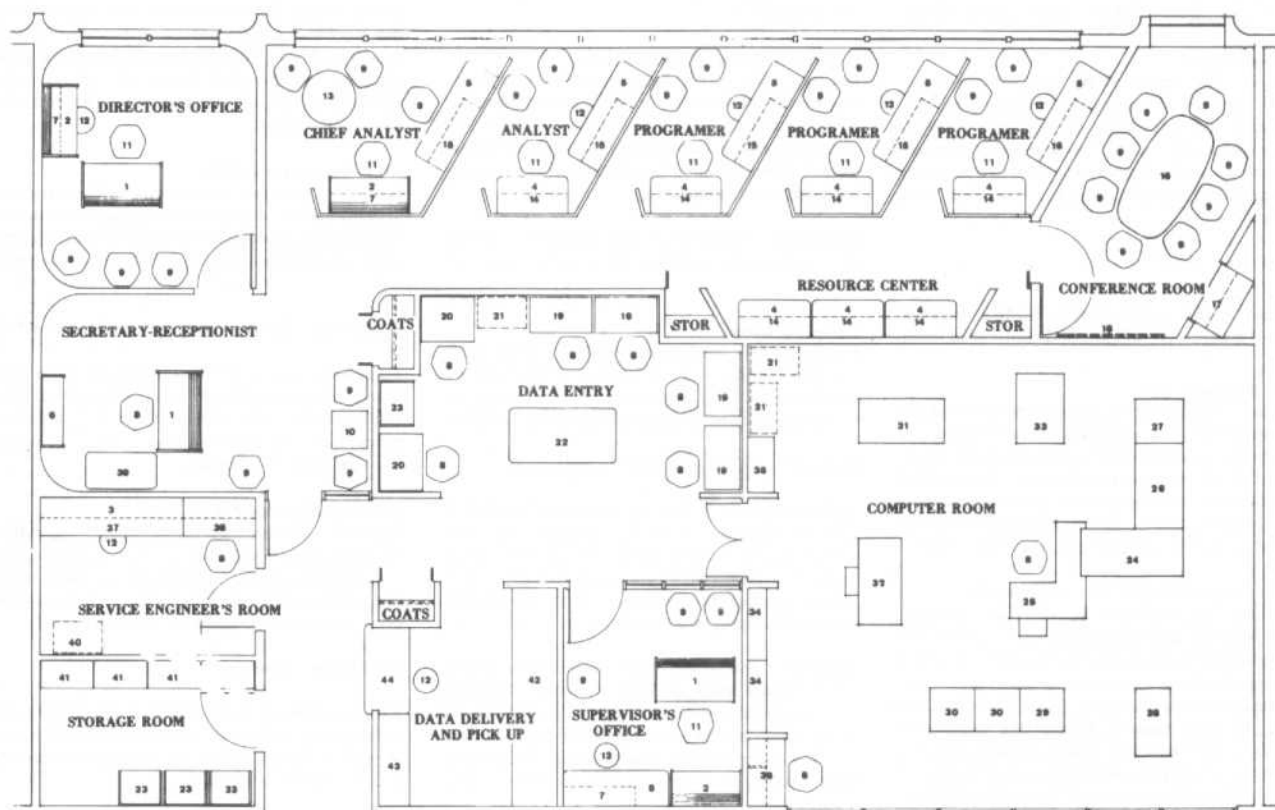

Every problem processed in a computer must be carefully analyzed so that exact and logical steps for its solution can be worked out. This preliminary work is generally the responsibility of the systems analyst. When it has been completed, the program or detailed instructions for processing the data can be prepared by the programmer. Exactly how he [she] does this depends not only on the type of computer hardware available but on the nature of the problem. These determine what programming techniques will be used. Still other techniques are required in writing aids which reduce the amount of detail associated with programming.

The programmer usually starts an assignment by determining exactly what information must be used to prepare assigned documents and their exact final format. He [she] then makes a flow chart or diagram that shows the order in which the computer must perform each operation and for each operation prepares detailed instructions. These when relayed to the computer's control unit, instruct the machine exactly what to do with each piece of information to produce the documents anticipated. The programmer also prepares an instruction sheet for the console operator to follow when the program is run on the computer.

The final step in programming is debugging or checking on whether the instructions have been correctly written and will produce the desired re-

Administrative Services and Facilities for Hospitals: A Planning Guide HEW Pub. No. (HSM) 72-4035. U.S. Department of Health, Education, and Welfare, Washington, D.C., 1972.

Fig. 2.

sults. A program is debugged in two steps. First the programmer takes a sample of the data to be processed and reviews step-by-step exactly what will happen as the computer follows the series of instructions which make up the program. Then, after revising the instructions to take care of any difficulties that have appeared, the programmer completes the test by making a trial run in the computer. The console operator sometimes helps with the latter part of the debugging process.

A simple program can be made for a computer within a few days; a complex problem may re-

quire many months. To improve efficiency, existing programs must be updated to keep pace with administrative changes. Introduction of larger or newer model computers often requires that many programs be rewritten.

Information to be processed by a computer is encoded first onto some type of medium which is compatible with the computer such as magnetic tape, paper tape, or punchcards. Most computers are designed to accept data in punchcard form.

Occupancy One E.D.P. programmer and seating for one visitor per office or work station. A total

of three offices or work stations is assumed for the medium system E.D.P. programming area.

Adjacent Areas E.D.P. secretarial office, systems analysts' offices, E.D.P. machine room, and E.D.P. supervisor's office. Convenient communication with the E.D.P. director's office, conference room, E.D.P. supply storage room, and data entry room is essential.

Conference Room

Function This area provides for private discussions, inservice education, and meetings.

HOSPITALS

EDP Unit

Occupancy Eight persons.

Adjacent Areas E.D.P. director's office, analysts' offices, programmers' offices, and resource center.

Resource Center

Function This area provides for a library of programs, computer literature, related files, and software required to facilitate an efficient operation. A resource center should provide work surfaces for analysts and programmers in order to minimize the amount of material stored in individual work stations.

Occupancy None.

Adjacent Areas E.D.P. director's office, analysts' offices, programmers' offices, and conference room.

E.D.P. Director's Office

Function This area provides for the E.D.P. director who with the concurrence of the hospital administrator is responsible for the total activity of the E.D.P. service system, including formulation, development, and implementation of overall policies, programs, plans, and procedures for control of the system in general and the E.D.P. unit in particular.

The director reviews and analyzes the various inter and intra workflow activities and methods of all hospital operating programs in relation to the total E.D.P. function. On the basis of these analyses, he [she] formulates and institutes management controls designed to improve the efficiency of the programs through the application of E.D.P. techniques with due consideration for quality requirements, optimum use of personnel and/or other resources, and time and cost limitations.

He [she] establishes training programs to orient hospital personnel in the potentials of the E.D.P. services and to teach them the methods and techniques which will enable them to fully utilize these services in their areas. He also institutes research activities to improve E.D.P. uses in the hospital and maintains a technical library of materials relative to all elements of data processing.

He [she] maintains statistical records as a basis for evaluating the effectiveness of the service and the improvement of the hospital's operation through the use of E.D.P.

He [she] provides advice and exchange of information, resolves problems, and participates in meetings and conferences with key staff members and department heads to discuss present and expected work and to develop broad plans.

Occupancy E.D.P. director and three visitors.

Adjacent Areas

Shared terminal service system: E.D.P. secretarial office, systems analysts' office, and data entry and transmission room.

Medium system: E.D.P. secretarial office and systems analysts' offices. Convenient communication with the programming area and E.D.P. supervisor's office essential.

Data Entry Room (Medium System)

Function This area accommodates equipment and personnel necessary for encoding information onto computer compatible media for electronic data processing application. It also accommodates limited facilities for occasional card punching relative to programming.

Occupancy Three data entry operators and occasionally one programmer for a short period of time.

Computer Room

Function This area accommodates most basic electronic equipment or hardware required for the electronic data processing activities program. Limited expansion and access space are essential.

Occupancy One operator for each shift.

Adjacent Areas E.D.P. supervisor's office, E.D.P. service engineers' workroom, programming area, data entry room, and data delivery and pickup area. Convenient communication with the E.D.P. director's office, the systems analysts' offices, and the E.D.P. supply storage room.

Comment The raised floor of this area allows future layout changes with minimum alteration cost, protects interconnecting cables and power receptacles, provides personnel safety, and permits the space between the two floors to be used for air supply ducts or as a plenum where necessary.

The environment for this room area should be maintained at 75°F. and 50 percent relative humidity. The air should be supplied through a filter of at least 90 percent efficiency based on the National Bureau of Standards discoloration test using atmospheric dust. Use of the space beneath the raised floor as a plenum will depend upon the recommendations of the electronic equipment manufacturer and the design engineer. Pressurization to minimize dust infiltration from adjacent areas is an important consideration.

To function properly, magnetic tapes require the same temperature and relative humidity levels as the electronic hardware. Because of this, and also for their easy retrieval, those tapes in frequent use are generally stored in cabinets and shelf tables within the computer room. Sometimes a separate storage room remotely located is provided for extra protection of vital records. These include master tapes which would be irreplaceable or those which would be needed immediately after a fire or could not be quickly reproduced. If an approved data safe is provided for storage of vital records, it can be located within the computer room.

In laying out a computer room, the manufacturer's specifications regarding maximum lengths for the control cables which interconnect the various machines and the minimum service clearances for the machines should not be exceeded. Another important layout consideration is adequate working area for operating personnel and space for auxiliary equipment such as worktables, cabinets, and utility trucks.

E.D.P. Supervisor's Office

Function This area accommodates the supervisor responsible for the physical production aspects of the E.D.P. operation, for quality controls, and some cooperative functions relative to programming.

Occupancy E.D.P. supervisor and two visitors.

Adjacent Areas E.D.P. machine room, data entry room, and data delivery and pickup area. Convenient communication with the E.D.P. director's office, E.D.P. programming area, and E.D.P. supply storage room is essential.

Data Delivery and Pickup Area

Function This area serves as a receiving station for unprocessed data and also as a pickup point for processed data. Decollating, bursting, collating, and binding of data forms and documents prior to pickup are done in this area.

Occupancy One person.

Adjacent Areas Data entry room, E.D.P. machine room, and administrative corridor. This area should be visible and easily accessible from the E.D.P. supervisor's office.

E.D.P. Service Engineer's Room

Function This area facilitates the maintenance and service engineering activities essential to the continuing operation of the E.D.P. equipment.

Adjacent Areas E.D.P. machine room.

Occupancy One person.

E.D.P. Supply Storage Room

Function This area provides readily available holding space for short-term inventories of standard and special machine-mated paper forms. It also provides holding for a small reserve of new magnetic tapes, and in the case of the medium system E.D.P. unit, a small reserve also of blank cards. A one-week supply of forms is generally preferred holding.

Occupancy No permanent personnel.

Adjacent Areas Data delivery and pickup area to be easily accessible to the data entry room, the E.D.P. machine or transmission room, and the administrative corridor.

By F. CUTHBERT SALMON, AIA, and CHRISTINE F. SALMON, AIA

Planning means thinking in terms of spatial and human interrelationships.

The interrelationships between the several areas of activities are varied and complex; add to these the problems of site selection, considerations of finance, and provision for future expansion, and it becomes apparent that sound planning requires rigor and thoroughness. (See Fig. 1.)

One of the most basic planning principles is organization: the best organization for the purpose intended. When that purpose is rehabilitation, one must take into account the limited mobility and acute sensitivity to physical environment of those for whom the building is intended.

With limited mobility, the wheelchair becomes a basic unit or module of design. The range of the dimensions of a standard wheelchair must be borne in mind. Design is governed not only by these basic dimensions, but also by the dimensions of the paths of action of the chair. Variations in disability permit variable limits of maneuverability, and the relationship of the wheelchair to basic equip-

ment must also be recognized in the development of the planning data.

MEDICAL

The medical area of a rehabilitation center provides the following services: medical evaluation, performed by the physician and his staff; physical therapy, including hydrotherapy; occupational therapy; speech and hearing therapy. It also furnishes the services of a prosthetic and/or orthotic appliance shop. The detailed character of the medical area will vary with the program of the center itself.

The emphases in the medical program will be determined by the needs of the patients and by already existent community medical facilities.

The medical area provides the basis for the patients' total program at the center. It must be accessible to all other areas and be well integrated with the administration and admissions services. (See Fig. 2.)

This section will contain much specialized examination, treatment, and therapy equip-

ment. Some of this will be heavy, requiring a floor designed to accommodate such concentrated loads; the electrical service to these machines is important.

Patients will be wearing lightweight examination or treatment gowns here, and the heating system will have to compensate for this. The records for all sections of this area are extensive; therefore, adequate storage for them is mandatory. Conferences with patients and staff make further demands on the available space. Many different kinds of activities will be housed here and the space needs to be adjustable accordingly. Accessibility to all other areas is also essential for the medical area of activity.

Physician

Medical diagnosis is the basis for development of the patient's successful rehabilitation program.

On admission, a medical examination is essential, whether the patient is prescribed a program in one or several of the center's areas of activity: physical medicine, social adjustment, or vocational rehabilitation. A nurse is usually present during the examination.

Complete evaluation of the patient may require the services of consulting medical specialists, staff specialists in the several medical therapies, psychologists, social workers, and vocational counselors. A total integrated program is developed for the patient, with medical considerations as the initial frame of reference.

Location Within Building As all patients receive medical evaluation, the physician's unit should be near the center's main entrance.

For purposes of admission, and for the keeping of records, location of the unit near the administrative department is desirable.

If an in-patient nursing unit is included, the physician should have, if possible, convenient access to the nursing unit.

In smaller centers, the main waiting room for the building may serve as the waiting area for the physician's unit.

Place the unit in a quiet zone.

Staff-Patient Ratios The physician-patient ratio will depend entirely on the nature of the program. Centers accommodating in-patients will necessarily need a greater amount of physician service per patient than the out-patient type of center.

Physician-patient ratios can be established only on an individual basis.

Organization of Space The physician's unit should form a self-contained area, with access to the consultation room and the medical examination room by means of a subcorridor, if possible.

To make full use of the physician's time, there should be two examination rooms for each consultation room.

Recommended for the area is a toilet designed for wheelchair occupancy, accessible from the examination room.

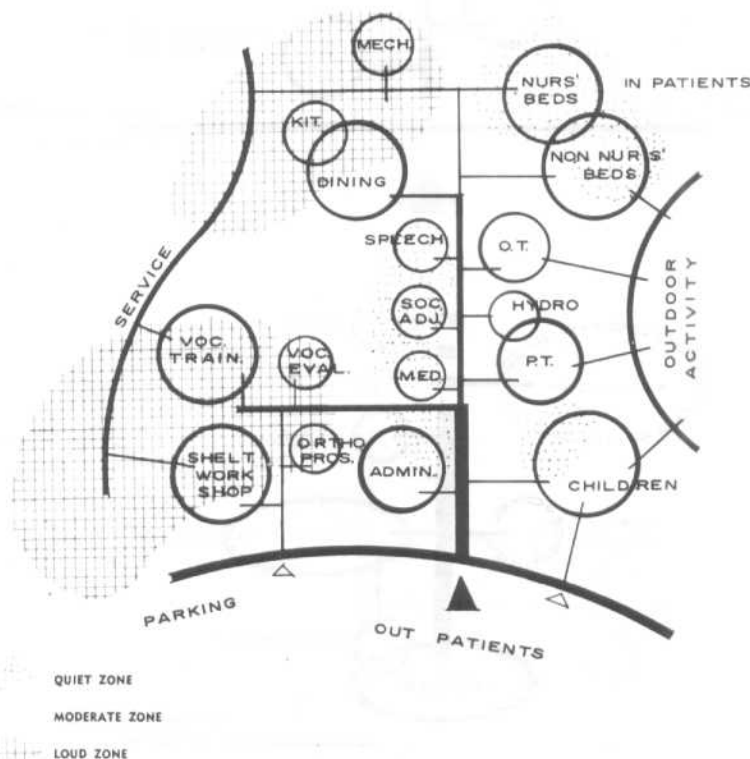

Fig. 1 Interrelations of main elements of space of a rehabilitation center. Activities may be grouped according to relative noise levels.

REHABILITATION CENTERS

Although a clinical scale is essential equipment for the examination room, a wheelchair patient's scale constructed from a modified platform scale is very desirable. These scales should be conveniently accessible from the other parts of the building and may be placed in the physician's unit, or near the physical therapy exercise room or gymnasium.

Waiting Room Arrange the furniture to allow space for wheelchair patients. Also, include coat hanging facilities.

Secretary Include in the furnishings a secretary's desk, writing table, and letter size file cabinets.

As certain records must be available to department heads in other areas of the center, placement of such files in the central records room of the administrative area is the usual practice. However, some centers prefer to keep medical records in the physician's unit. A physician's records are traditionally privileged communications, and, if kept in the central records room, should be made available only to the responsible professional personnel.

Consultation Room Include in the furnishings for the physician's office and consultation room an executive desk and chair, bookshelves, and film illuminator. Allow space for two visitors' chairs and a wheelchair. Provide a convenient coat closet. (See Fig. 3.)

Examination Room Include in the furnishings for this room an examination table with clearance on all sides, an examination light, a lavatory and mirror, clinical scales, a film illuminator, an instrument and supply closet, a small electric pressure sterilizer (if no lab-utility room is provided), and a chair. Standing bars are optional equipment.

Lab-Utility Room If a lab-utility room is provided, equip it with a pressure sterilizer, sink, plaster cart, work counter, and storage cabinets.

Radiology Radiology is usually provided for rehabilitation centers by x-ray departments of hospitals, clinics, and other institutions. If radiology is to form a part of the center's services, standard practice in the design and construction of the department should be followed. (See Fig. 4.)

Physical Therapy

Physical therapy is administered under medical supervision and performed by graduates of a school or course approved by the Council on Medical Education and Hospitals of the American Medical Association.

The objectives of physical therapy are to correct or alleviate bone and joint or neuromuscular disabilities. This entails a concern with all types of physical disabilities, such as neurological diseases, arthritis, amputation, paralysis, spasticity, structural and postural malalignments, crippling accidents, postsurgical conditions, etc. Measures are used to retain or reestablish circulation, muscle tone, coordination, joint motion leading to mobility, ambulation, and activities of daily living.

In carrying out his aim, the therapist will make use of heat, cold, water, light, and electricity as well as the training effects of active, passive, resistive, and reeducation exercises.

Organization of Space There should be two major treatment areas, dry and wet. The dry area includes the exercise room or gym and treatment

cubicles; whereas the wet area includes all hydrotherapy treatment, tanks, pools, and related facilities.

Hydrotherapy equipment should be grouped in one area, separate from, but adjacent and accessible to other treatment areas.

Space considerations for a physical therapy department must take into account circulation areas for patients and staff. Situate the equipment for efficient and safe use, and provide storage space for equipment and supplies.

Flexibility and expansion of facilities should be considered in basic planning to meet changes in requirements.

It is advisable to consult with the chief physical therapist, the center's director, and the center's physician to determine equipment needs and the program of activity for this department.

Location Within Building The place for physical

and occupational therapy, as well as for activities of daily living, should be in close proximity, as many patients will receive treatment and training in all three areas.

Arrange the areas so that scheduled patients may proceed directly to physical therapy without interfering with circulation to other departments.

As physical therapy may take advantage of certain outdoor activity, place the exercise room or gym near the outdoors.

As physical therapy involves some noisy activity, this area should be removed from quiet zones, such as the place where speech and hearing therapy is administered, or the nursing unit. (See Fig. 5.)

The area should be convenient to the center's physician and the nursing unit (if provided).

Staff-Patient Ratios One physical therapist can treat an average of 10 to 15 patients per day.

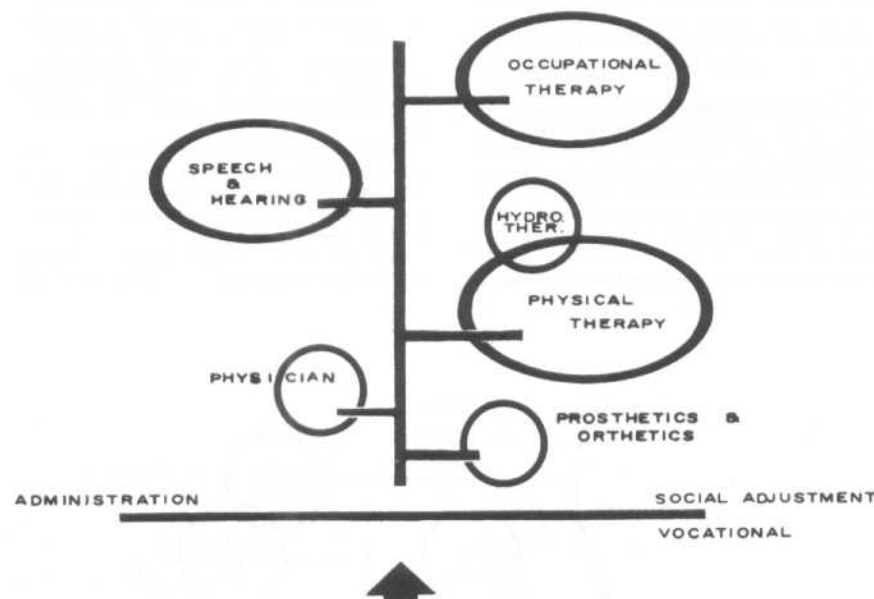

Fig. 2

Fig. 3

Fig. 4

Fig. 5

Group services may increase this to 20 a day.

If the physical therapist is assisted by nonprofessionals and if the work space and scheduling are well planned, a maximum staff-patient ratio may be achieved. Nonprofessional assistants, paid or volunteer, can be trained to prepare patients for treatments, attend to equipment, and transport patients, if necessary.

There are many variables involved in staff-patient ratios.

Treatment Cubicles Divide the cubicles with curtain tracks for easy access by wheelchair and stretcher patients and for flexibility in use of space, as for instructional activity or gait training. Curtains should not extend to the ceiling or floor, so that when drawn, they may not interfere with ventilation. (See Fig. 6.)

Equip cubicles with a treatment table with adequate work space on each side and at the head. Treatment tables with drawers or shelving provide convenient storage space for sheets and other requirements.

Provide in the cubicles a place for the patient's outer clothing, such as hooks or lockers.

Provide a lavatory convenient for the therapist's use.

REHABILITATION CENTERS

Fig. 6 Treatment cubicles and examination room.

Equipment for this department may include infrared and ultraviolet lamps, diathermy, hot pack and electrical stimulation apparatus, ultrasonic equipment, suspension apparatus (Guthrie-Smith), electrical diagnostic apparatus, moist heat equipment, sand bags, powder boards, powder, oil or lotion, alcohol, and linen.

In many cases patients will be lying on their backs during treatments. Ceiling lighting should be indirect or semi-direct to avoid glare. Therapists making tests or examinations require shaded or nonglare spotlights.

Waiting Area Provide space for wheelchair and ambulant patients; and if there is a nursing unit, space also for a stretcher.

Place the therapist's office near the waiting area for control.

From the waiting area, the patient should be able to go to the exercise room, hydrotherapy, or treatment cubicles with a minimum interference of activities.

Therapist's Office There should be staff office space for interviewing patients and attending to administrative duties, as well as space for

files, and a desk with a dictating machine.

Partition the office so that interviews may have acoustical privacy.

Situate it near the patients' entrance to the physical therapy department and design it to provide maximum supervision of activities.

A patient scheduling board and writing surface are recommended. Locate them conveniently for all physical therapists.

Staff lockers and dressing rooms (separate from patients) should be near this department.

Examining Room The room should be convenient to the entrance of the physical therapy department.

Equip it with an examination table, lavatory, and space for examination equipment.

Provide floor-to-ceiling partitions for privacy.

The room may be used for special tests and measurements, or for treatment when privacy is desirable.

Scales for weighing patients (including patients in wheelchairs) are sometimes provided in this room.

Exercise Area This area should be a flexible, clear space for individual and group exercise activities. (See Fig. 7.)

The most frequently used items of equipment are: exercise mats (sometimes raised 24 in. off the floor for the convenience of therapists and wheelchair or crutch patients—if area is of sufficient size, mats may remain in place), shoulder wheel, shoulder overhead and wall weights, shoulder ladder, steps, curbs, ramps, stall bars, parallel bars, posture mirror, stationary bicycle, counterbalanced and individual weights, sand bags, and paraffin bath. Some of this equipment may be made by a skilled carpenter rather than purchased. Purchased equipment should be accompanied by satisfactory repair and maintenance service.

Certain equipment relationships should be maintained. Place the posture mirror 4 ft from the end of the parallel bars. When mats and other movable equipment are removed, there should be sufficient space for gait training, also related to a posture mirror.

Doors to the exercise area should be wide enough to accommodate not only patients but also equipment. Double doors, each 3 ft wide, are recommended.

The layout shown suggests a minimum exercise area for a physical therapy department with one therapist and an aid. For an expansion

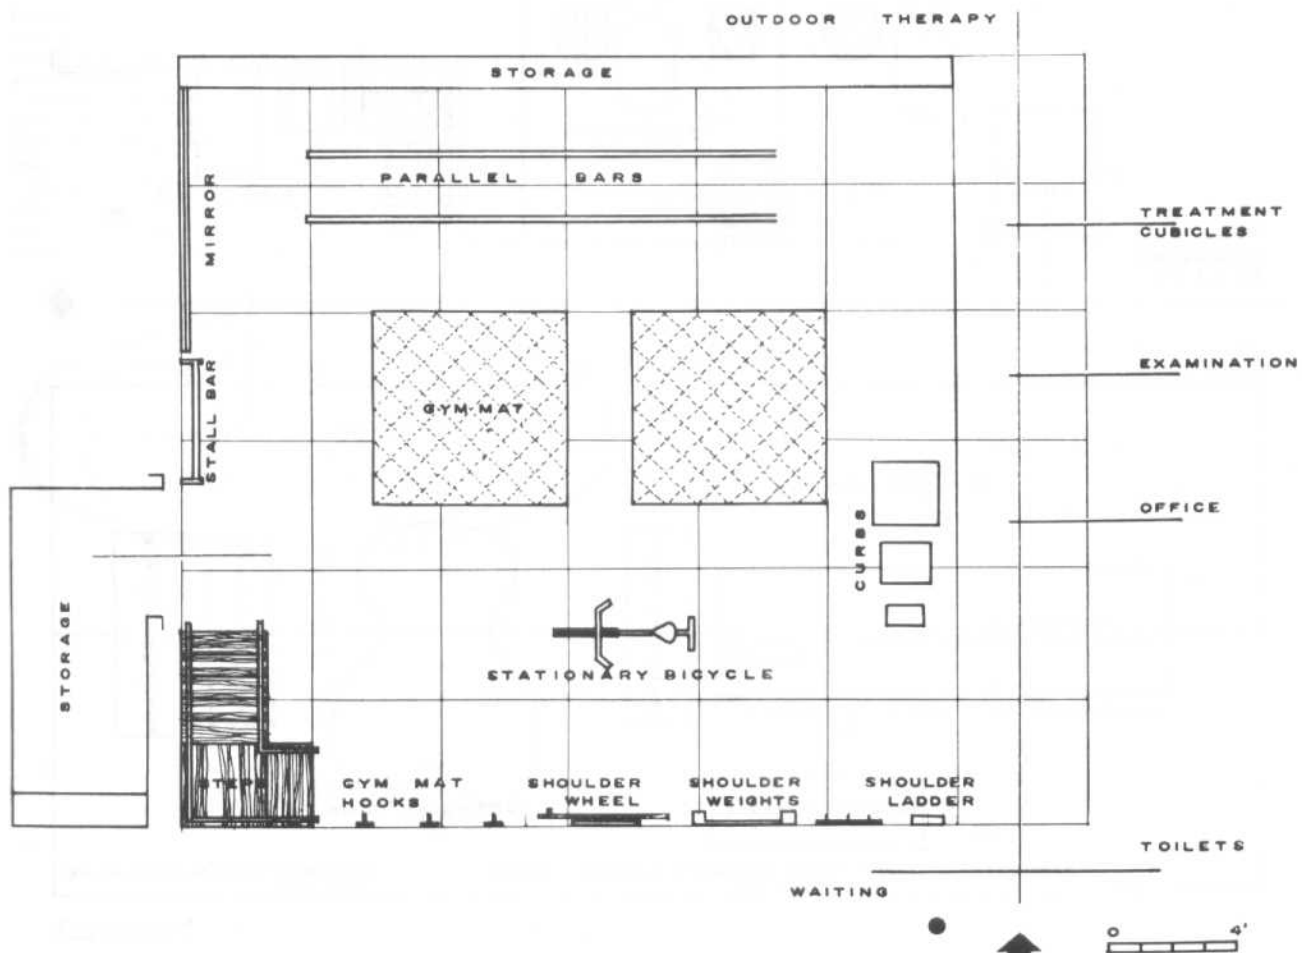

Fig. 7

of the exercise area see "Gymnasium" in this section.

The exercise area may be divided by open partitions which allow for the attachment of equipment and subdividing of activities, yet which permit circulation of air and easy supervision of the total area.

An observation cubicle with one-way vision glass may sometimes be used to advantage in order that visitors will not interfere with patients' activities.

Reinforce the walls for installation of exercise equipment, such as stall bars.

Provide storage for equipment not in use. Toilets should be accessible to the patients and designed for those who are confined to wheelchairs.

A wall clock in the room for timing exercises is recommended.

Vinyl wall covering to a minimum height of 5 ft will protect walls and ease maintenance.

There should be adequate ventilation. Fresh air without drafts in the exercise and treatment cubicles is very important. Air conditioning of this area is highly desirable.

Windows or room exposure should be designed to provide privacy within the exercise room.

Gymnasium In larger centers or centers with inpatients, a gymnasium is recommended. It

serves a variety of uses, such as individual and group exercises, recreational programs, and meetings.

The gymnasium will augment the program of the physical therapy exercise room, permitting the therapist to conduct group wheelchair and mat classes. The room should be furnished with parallel bars, wall bars, stairs, curbs, gradients, wall mirrors, etc., for individual instruction.

The room will also be used for recreational activity such as group volleyball, basketball, moving pictures, and wheelchair square dancing. A minimum clear ceiling height of 14 ft is recommended. If the gymnasium meets standard space requirements, rental of its use to community athletic organizations will be facilitated. Providing a recreational program is particularly important where inpatients are involved.

The gymnasium will also be used by the social group worker in the social adjustment program of some patients.

As the gymnasium is a multipurpose room, equipment and furniture within the area should be movable. Provision for its storage is essential.

As a meeting room to be used by selected groups within the community, this facility provides an excellent opportunity to acquaint the public with the problems of rehabilitation

and to arouse interest in the center's program. For this purpose, the gymnasium should be easily accessible to the public.

To make maximum use of this multipurpose room, it is important that activities be controlled to avoid conflicting schedules.

Hydrotherapy The space for hydrotherapy is frequently the most expensive area of the center; consequently, it should be planned with considerable selectivity.

Whirlpool tanks for arm, foot, hip, and leg immersion are considered inadequate by many centers serving multiple disabilities unless augmented with facilities for complete body immersion. (See Fig. 8.)

Almost all exercises and treatments can be conducted with a Hubbard tank and a wading pool and tank. Combinations of Hubbard tanks with wading facilities are available where space is limited.

Therapeutic pools are expensive to construct; consequently, they are usually considered only for larger centers.

All hydrotherapy activities require linen and towel storage. Also provide a wringer and dryer for bathing suits and a storage space for wet and dry bathing suits of both staff and patients.

Tank and pool areas require storage space for wheelchairs and stretchers, adequate

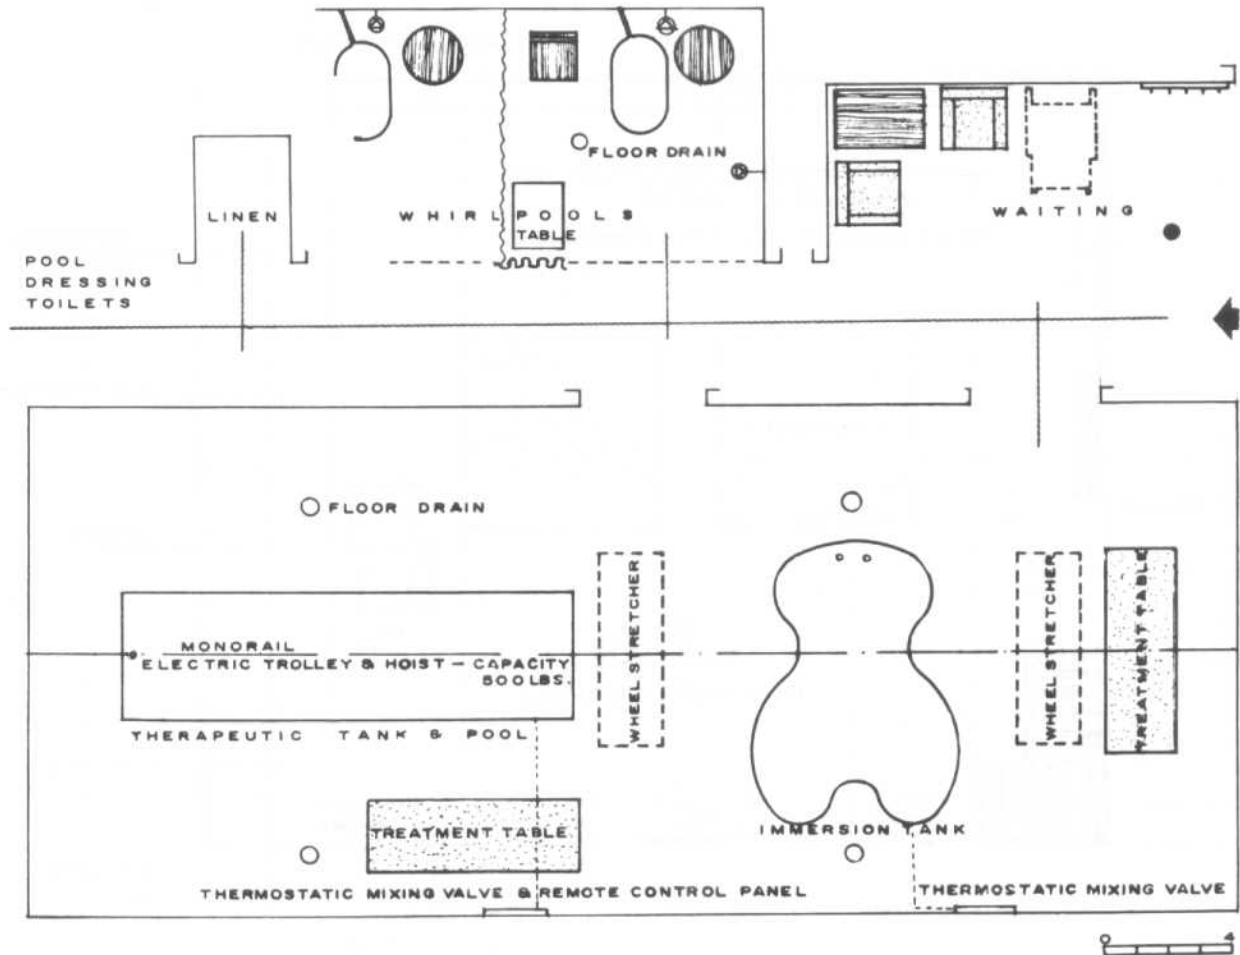

Fig. 8 Whirlpools and tank room.

dressing cubicles, or dressing rooms to permit maximum use of pool, showers, and toilet facilities.

As hydrotherapy is a moderately noisy activity, it should be removed from areas requiring sound control.

Floors should be of unglazed ceramic tile with drains for spilled water and tank overflow.

As equipment is heavy when filled with water, a structure must be designed for these additional loads.

Overhead monorails with lift mechanism are essential for efficient use of Hubbard tanks and waders. Ceilings should be a minimum of 9 ft 6 in. The location of the monorail with proper relationship to equipment is essential.

All pipes for hydrotherapy should be accessible but concealed. Waste lines should be adequate for rapid changes of water.

All hydrotherapy equipment should have thermostatically controlled mixing valves. Adequate pressure and an ample source of 160° F. water are essential.

Humidity reduction is a major concern in planning the hydrotherapy department. Adequate air conditioning is essential for the comfort of patients and staff.

Whirlpools This includes equipment for the treatment of arms, hips, and legs. Some models are available as movable units, in which case a

sink or lavatory is required in the cubicle for drainage of the unit.

Provide space for chair, table, and a stool of adjustable height.

In small centers where hydrotherapy equipment consists only of whirlpool tanks, place them near treatment cubicles and near the exercise room for easy supervision by the therapist.

Tank Room A treatment table with storage space is an essential requirement.

Allow space for wheel stretchers and provide 44-in.-wide doors. (A 56-in.-wide opening is necessary to install combination treatment and wading tank.)

Allow space for stretcher and wheelchair storage.

Showers and Dressing Rooms Directly related to the efficient use of a hydrotherapy pool is the provision of adequate dressing room facilities.

Dressing facilities do not necessarily have a size relationship to the pool indicated. For example, some programs will require several dressing tables in order to accommodate the patients.

Hydrotherapy Pool Many variations in size are possible.

The depth of the pool should be graduated. Variations of depth in 5-in. increments are

recommended. For children the shallow end should be 2 ft deep, for adults, 3 ft. The deep end of the pool should be 5 ft.

There should be a continuous gutter around the pool for the use of the patients and for the purpose of attaching plinths.

A portion of the floor surrounding the pool may be depressed to form an observation area for the therapist.

Occupational Therapy

Occupational therapy is administered under medical supervision and performed by graduates of schools of occupational therapy approved by the Council on Medical Education and Hospitals of the American Medical Association.

The objectives of occupational therapists are to assist in the mental and physical restoration of the disabled person, enabling him to adjust to his disability, increase his work capacity, and to want to become a productive member of his community.

In addition, the occupational therapist is concerned with the training of patients in the activities of daily living.

To achieve these goals, occupational therapy utilizes, on an individual basis, remedial activities which are found in creative skills and manual arts. (See Fig. 9.)

Location Within Building Occupational therapy should be adjacent to the physical therapy department, since many patients will use both areas.

Locate the area so that scheduled patients may proceed directly to occupational therapy without interfering with the circulation of other departments.

As some phases of occupational therapy involve noisy activity, this area should be removed from quiet zones in the building, or provision should be made for acoustic control.

Certain occupational therapy activities, such as those characteristic of daily living, may be conducted out of doors in favorable weather. It is recommended that, if possible, access to an outdoor area be provided.

The area should be accessible to the center's physician, the social adjustment area, and the vocational counseling area. As occupational therapy involves coordination with the nursing unit (for dressing and toileting particularly), the occupational therapy department should be conveniently related to it.

Staff-Patient Ratios One occupational therapist can treat eight to fifteen patients per day. The number of patients depends upon types of disabilities and the severity of the cases.

Where highly individual treatments are required, the daily load will decrease. Also, if the therapist is relieved of administrative responsibilities and assisted by nonprofessional persons, the daily load will increase.

For orthopedic patients, special equipment must frequently be devised under close supervision of the occupational therapist.

There are many variables applicable to staff-patient ratios.

Organization of Space The activity area may be so planned that each activity has a separate unit, or it may be planned to separate quiet from noisy and dusty from clean activity. The unit system facilitates assignment of special instructors to special activities and is also a more orderly arrangement of the space. However, this method increases the number of staff, makes supervision more difficult, and can be considered only in larger departments.

The activities of daily living (ADL) area, which is used to teach the patient how to live self-sufficiently in his home environment, should be closely related to the main occupational therapy treatment room.

As the occupational therapist works closely with the social adjustment staff and the vocational counselors, his office should be near their areas.

Activities of Daily Living The activities which are indicated include most situations found in the home (see Fig. 10).

Some training, particularly bathroom and

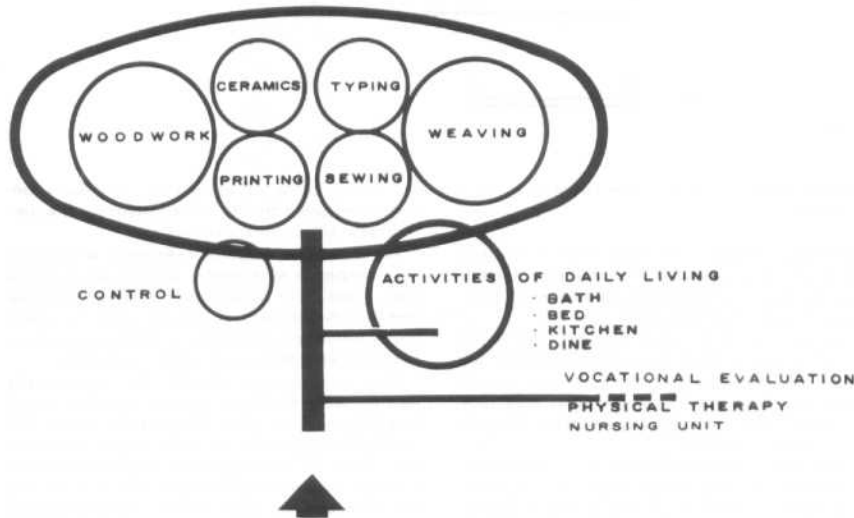

Fig. 9

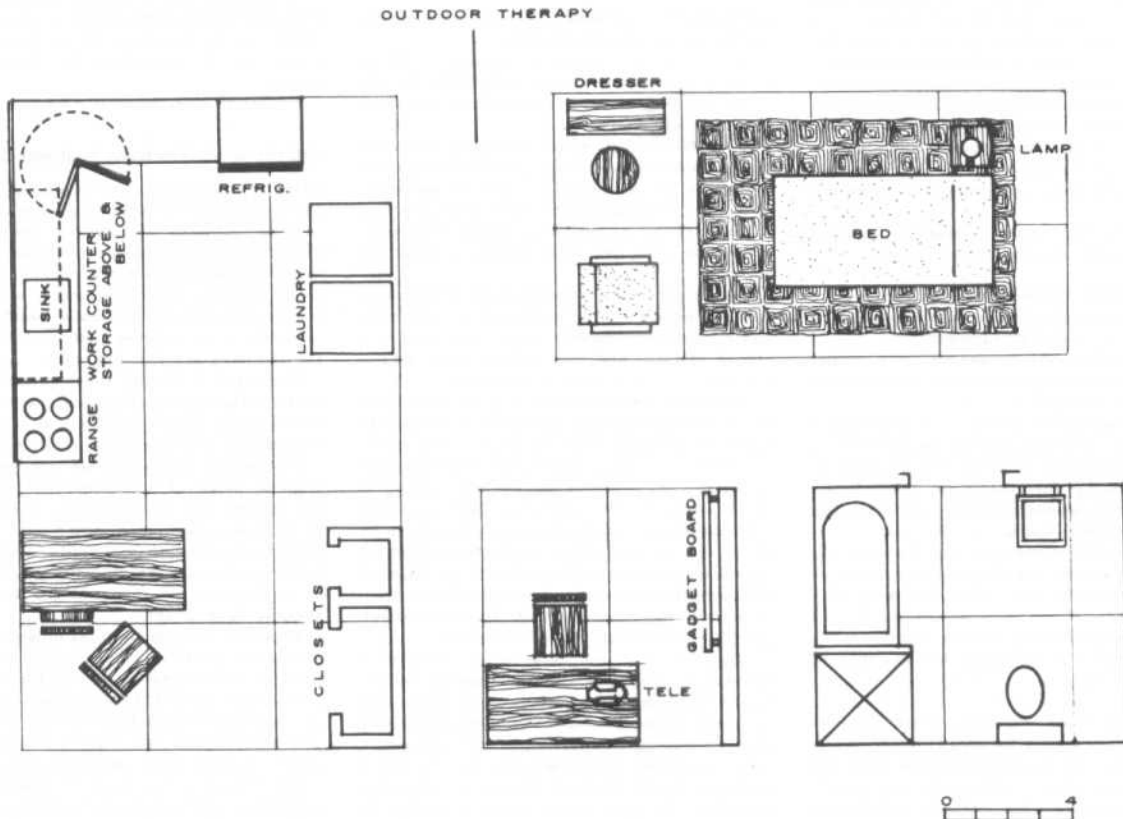

Fig. 10 Activities of daily living.

REHABILITATION CENTERS

bedroom activities, will require cooperation with physical therapists. Consequently, the ADL area should be easily accessible from the physical therapy department.

A gadget board containing numerous items of hardware, light switches, faucets, and other items frequently used should be included. The board should be adjustable in height.

The bathroom should be arranged to accommodate wheelchair patients (see "Inpatients").

The kitchen plan may include, in addition to the type illustrated for wheelchair use, standard counter and cabinet arrangements to test the patient's ability to cope with "normal" situations. Counters of adjustable height may be used to advantage in training patients.

A front loading washer and dryer, as illustrated, is desirable for wheelchair patients. Controls at the front of the range are recommended. However, the purpose of this training is to show the patient how he may use, if possible, appliances that are standard in his community.

A standard clothes closet is recommended as a part of the training in dressing.

A broom closet, vacuum cleaner, and adjustable ironing board should also be included.

Table space should be provided for training in eating and for use as a writing surface.

A rug can also be used to test the patient's ability to cope with that type of floor covering.

Speech and Hearing

The speech and hearing unit serves those with disabilities of deafness, stuttering, or delayed speech and voice disorders which may result from various basic abnormalities, diseases, or injuries.

A wide variety of programs is possible. Some provide for treatment of postoperative disorders resulting from tonsillectomies and ear operations, cerebral palsy, meningitis, cleft palate, hemiplegia, vocal cord anomalies.

Services may range from testing and treating of all conditions to emphasis on disorders associated with certain specific disabilities.

The center may include speech therapy only or audiological testing as well.

The program may serve adults or children, or both.

The center may include a teaching and research program in speech and hearing.

Staff-Patient Ratios Although ratios vary widely with different patients, an approximation of staff-patient ratios is as follows:

1. For audiometric screening: one audiometric technician may screen one patient every five to eight minutes.
2. For audiometric testing: the audiologist may test four to eight patients per day during the initial screening process. For a complete test for hearing aid evaluation, three hours is needed per patient, and the test is usually conducted in two visits.
3. For individual therapy: one therapist for six to ten patients per day (one half-hour to one-hour periods). The audiologist may also act as therapist.
4. For group therapy: five to eight persons per therapist; one therapist for twenty-four patients per day.

Organization of Space Patients' toilet facilities and coat racks should be accessible from the waiting room. It is recommended that the sound control room, test room, and audiometric testing rooms be located on a subcorridor off the waiting room in order to reduce noise. In a children's program, a play and ex-

Fig. 11

amination room near the test room is recommended.

Audiometric Testing The audiometric testing room (or, in some cases, booths) is a facility for pure-tone threshold testing and short form hearing screening tests (see Fig. 11).

Space should be provided for the audiologist's desk with an audiometer and one patient's chair or wheel chair. Furniture should be arranged so that the audiologist may face the patient and operate the audiometer. Provide storage and shelving.

The room should be treated acoustically for an overall residual noise level of not more than 40 decibels as measured on the "C" scale. This involves the treatment of walls, ceilings, and floors. (See Fig. 12.)

Control Room and Test Room This facility is essential for an audiology program.

It is preferable to place these rooms off the subcorridor or hall, and to control the activity in surrounding rooms in order that extraneous noises be eliminated.

For a children's program it is highly desirable that, outside the test room, a play and examination room be provided to accustom the child to his environment and to make the transition to the test room as easy as possible. This room should be equipped with children's furniture and toys.

Equipment for the control room will include a work surface for the audiometer, earphones and microphone, tape recorder, and tape and record storage, and may include other equipment such as a Bekesy audiometer.

If hearing aid evaluation is part of the program, provide storage space for hearing aids either in the test room or the control room.

The control room should be treated acoustically to achieve an overall residual noise level of not more than 40 decibels on the "C" scale.

An observation window approximately 18 by 20 in. is required. For adequate control of sound transmission, three pieces of glass of different thicknesses and nonparallel in construction are recommended. One-way vision glass in the control room is optional.

Equipment for the test room includes a speaker, microphone, and headphone. Microphone and headphone jacks should be located near the patient's chair. Additional auxiliary wall- or ceiling-mounted speakers are sometimes provided, particularly for the testing of children. These speakers should be separately switched. All this equipment is wired to the audiometer. Additional spare jacks in both the control and the test room are recommended

for other items of equipment. Conduits between the jacks should be installed in a manner that avoids sound transmission.

For complete diagnostic service, a galvanic skin response audiometer may be used in the test room. For diagnostic testing, delayed auditory feedback equipment may be used. For a children's program, children's furniture and toys should be part of the test room.

The test rooms should be acoustically treated to achieve an overall residual noise level of not more than 30 decibels on the "C" scale. This requires carefully supervised construction of a "floating room." In new construction the subfloor may be depressed to eliminate the high step or ramp at the entrance to the test room. If built on grade, the floating slab for the room may be placed on a sand bed.

To achieve this degree of acoustic control, it is essential that the floating room have adequate "mass" and that all necessary precautions are taken to avoid the conduction of sound.

Proper air circulation is a frequent problem.

Orthotic and/or Prosthetic Appliance Shop

Orthotic appliances are medically prescribed for the support of weakened parts of the body and to increase or control their function. Prosthetic appliances are medically prescribed artificial substitutes for a missing body part. Such devices are constructed by orthotists and prosthetists in cooperation with the physician, the physical therapist, and the occupational therapist. (See Fig. 13.)

The type of facility for orthotic and prosthetic services will vary widely with rehabilitation centers and is dictated at times by the availability of commercial services.

Frequently, arrangements are made for a representative of a commercial firm to visit the center. For this purpose a fitting room is recommended as a minimum facility, although an office or treatment cubicle is sometimes used and minor adjustments and repairs to appliances are made in the occupational therapy department.

However, a small shop (as illustrated) within the center provides close liaison between the patient, the medical team, and the orthotist or prosthetist. In such a shop, small devices such as feeders and page turners may be fabricated and adjustments and repairs made to wheelchairs, braces, limbs, and crutches.

If a minimum facility is established, consideration should be given to its future expansion, not only in terms of space, but with respect to electrical services, ventilation, gas supply, etc.

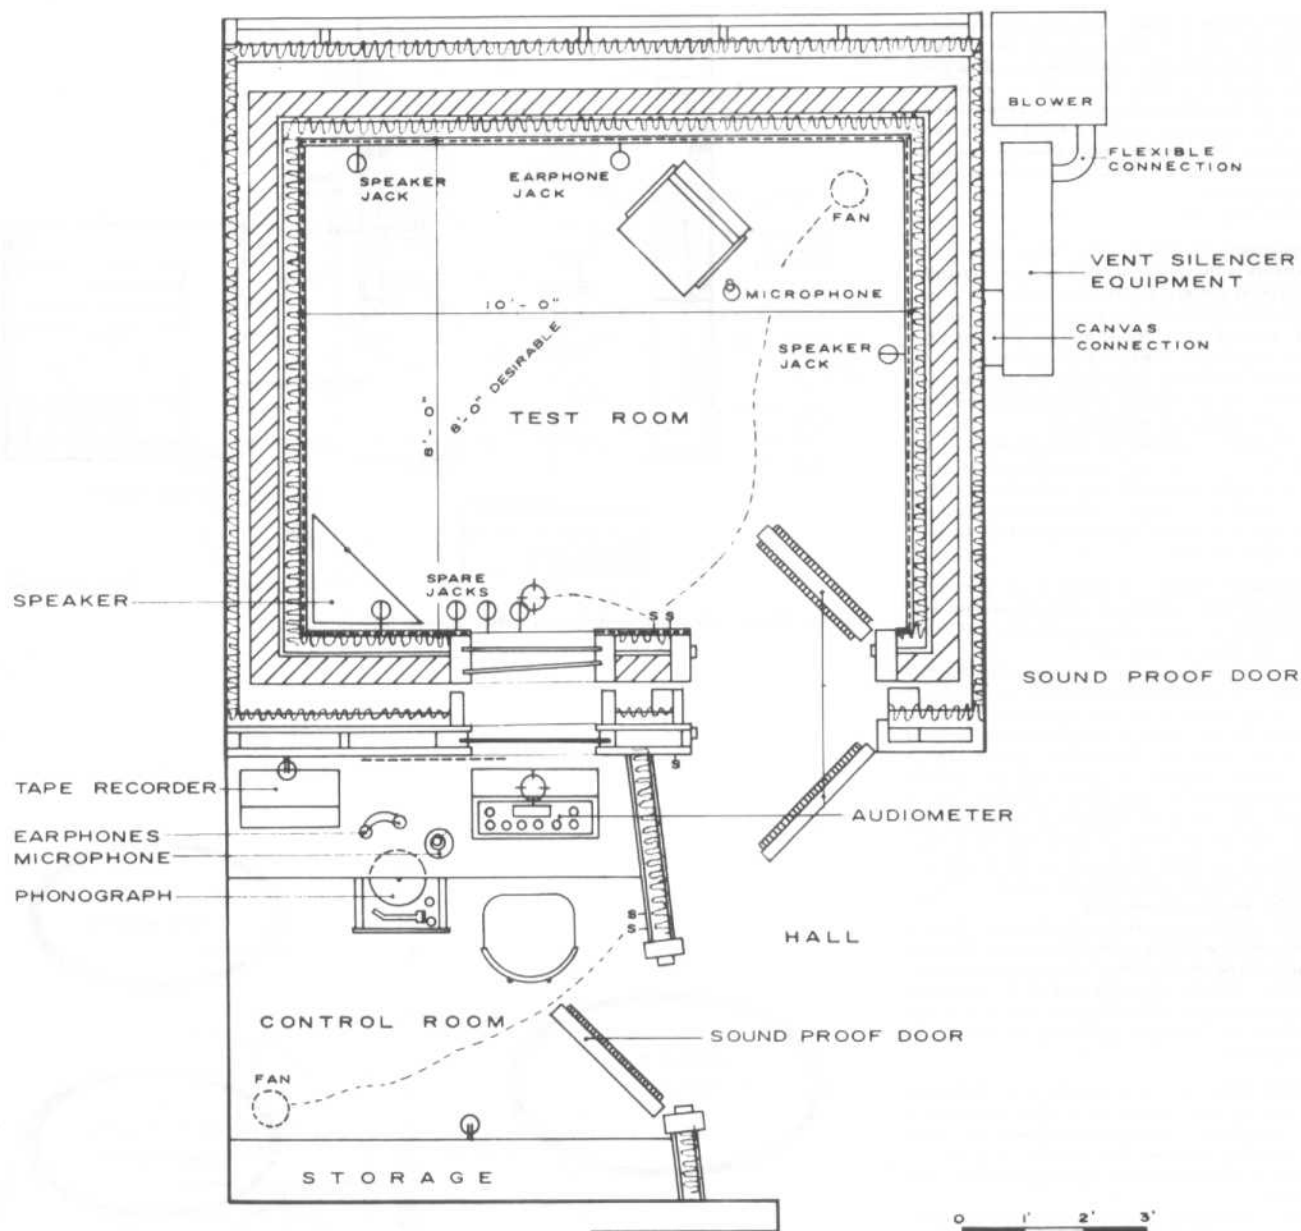

Fig. 12 Plan of typical audio-testing area.

The fabrication of major appliances requires much heavy and noisy equipment. Isolation of such a shop is essential to the control of noise and reduction of the fire hazard.

Location Within Building As the orthotic and/or prosthetic appliance shop will serve outpatients requiring minor adjustments or repairs to their devices, the unit should be easily accessible to entrances.

The unit should be located in a noisy zone, and, if possible, near the gymnasium, so that the patient may try out his prostheses or braces. The fitting room, however, may be made sufficiently large for this purpose.

SOCIAL ADJUSTMENT

Social adjustment requires psychiatric and social services for the treatment of social and emotional problems.

Psychiatric Service: Frequently the psychiatrist is employed on a part-time basis and is primarily called upon to provide the following services:

1. Psychiatric screening to diagnose emotional problems
2. Staff consultations on how these problems should be managed in relation to the patient's total rehabilitation program
3. In-service staff training for the purpose of developing greater understanding of the psychological factors in disability

Psychological Services include:

1. Psychological evaluation, accomplished by means of various psychological testing procedures and interviews which evaluate the patient's intelligence and personality
2. Interpretation of clinical findings to members of the staff
3. Counseling (therapy) on either an individual or a group basis, usually carried out with the psychiatrist and social service staff

4. In-service training of psychologists and participation in psychological research.

The minimum recommended psychological facilities would include a psychologist's counseling room and test room.

Social Services include the following:

1. Social study and evaluation, including the collection of relevant information from the patient, his family, and other agencies, and the appraisal of such information with respect to the patient's rehabilitation potential
2. Social casework, where the social worker (medical social worker or psychiatric social worker) works with the patient to improve attitudes toward self-support and motivation toward treatment and work
3. Social group work, including the correction of abnormal living patterns by using planned group activities, recreational in nature but therapeutic in value. It may include hobby activities, group discussions, and activities of an adult education nature.

REHABILITATION CENTERS

Location Within Building The services should be administered in a quiet area of the building.

As most incoming patients will receive some services in this area, it should be readily accessible from the main entrance of the building.

If the program involves large numbers of children, the psychological therapy room for children should be in the children's treatment-training unit.

(See Fig. 14.)

Organization of Space The flow pattern for patients within this area will vary considerably. A typical pattern for the evaluation of a new patient would have the sequence of receptionist, waiting room, social worker (for case history of patient), medical evaluation (for all incoming patients), psychological testing, and psychiatric screening. The two latter services are not needed by all patients.

Vocational counseling, and appraisal of the patient's employment potential in the vocational evaluation unit may also be included in the initial evaluation. Also for this purpose, audiometric screening and speech evaluation are often helpful.

Staff-Patient Ratios As psychiatric screening and psychological therapy will vary widely with individual patients, no approximation of staff-patient ratios is possible.

For psychological testing a recommended average is two patients a day per psychologist for brief psychological evaluations. This includes the time required for interpretation and writing reports. Extensive psychological evaluation requires one work day per patient, including time for preparation of the report. Other activities such as training, research, and therapy will detract from these averages. This does not provide for evaluation of vocational skills, aptitudes, and interests, which is a function of vocational services.

For social caseworkers, the number of cases per worker will vary with the number of intake studies and the number receiving continuing service. Where there is a balance between these two types of service, an individual caseworker may handle a caseload of from 25 to 35 patients.

Waiting Room If the program is of sufficient scope, provide a separate waiting area with a receptionist for the psychological-social unit. In smaller centers, this facility may be incorporated in the main waiting room for the center.

The receptionist schedules patient interviews with the psychological-social staff.

Access to interview and test rooms by means of a subcorridor will provide privacy and reduce extraneous noise from the rest of the building.

Psychological Training and Research Programs For a training program, provide observation facilities in the children's play therapy and activity group rooms, such as observation cubicles with one-way vision glass or, preferably, television cameras with screens in a central viewing room. (See Fig. 15.)

Provide a separate office for each psychological trainee.

Research programs are of a wide variety. Some involve much equipment; others, no equipment. Provide a separate area for this facility.

VOCATIONAL

The vocational area of a rehabilitation center provides the following services: counseling,

Fig. 13 Orthotic and/or prosthetic appliance shop (minimum facility).

Fig. 14

REHABILITATION CENTERS

Fig. 15

Fig. 16

evaluation, training, and placement; the sheltered workshop (or rehabilitation workshop) is part of this area, and in some cases, certain aspects of special education will be included. The vocational program is determined by the needs of the patients and the needs and opportunities of business and industry in the community served by the center. This program is a most important part of the patient's total rehabilitation process. (See Fig. 16.)

This area has the responsibility of acquainting the patient with situations in industry or in business and of preparing him for job competition. Realistically designed workshops and offices will be required to create a job situation atmosphere for the patient.

This area should present to the patient a very wide range of job possibilities. Few centers will contain an extensive number of job situations; some may have none if this need has been satisfied through the cooperation of a trade school or some other agency. Patients should not be trained for jobs which they cannot obtain later.

Changing types and techniques in industry make it essential that this area have maximum flexibility, especially in heating, ventilating, plumbing, lighting, electrical installations, and equipment placement. The vocational area must offer training in small segments of a job operation and present advanced types of vocational opportunities.

Vocational counseling provides an opportunity for the patient to obtain an understanding of his vocational abilities and potential, and to learn the scope of their possible application. The center may choose to work with cooperating counselors already established in the community, if it does not provide this service within the center. Sometimes counselors are loaned to centers by the State Vocational Rehabilitation Agency and conduct their work at the center.

Vocational evaluation is the process of collecting and appraising data on the patient's interests, aptitudes, and ability in work situations. This section needs to be quite broad in scope in order to find the vocation best suited and most satisfying to the disabled person. This section of the center's program is frequently referred to as a prevocational unit.

Vocational training provides the discipline necessary for the patient to attain his job potential established in vocational evaluation. Vocational training requires carefully supervised instruction in vocations best serving the patient's needs with full regard to employment possibilities.

Sheltered workshop provides employment for disabled persons within the center. This is productive work for which wages are paid; the work is usually obtained on contract or sub-contract basis. In this area, further vocational evaluation and training are possible.

Special education will be found in this area when enough patients have difficulties with certain areas of academic or vocational achievement. If children need this service, it may be located in their area. Frequently, this is provided through cooperation with the public schools.

Placement service is to be offered when the number of job placements and contacts warrants it; otherwise this service is performed by other agencies. In smaller centers placements may be handled by the vocational counselor. Placement may mean the patient's return to his former job, full employment by selective placement or partial or special employment either at home or in the sheltered workshop.

REHABILITATION CENTERS

Supervisors will be in charge of the separate units of this area and will be responsible for integrating their unit with the total vocational effort.

The director will be in charge of the total vocational area and responsible for integrating this area with the rest of the rehabilitation center program.

Vocational Training

Vocational training is prescribed after evaluation of the patient's abilities, interests, and job training has begun.

The vocational training unit provides opportunity for growth in ability and assurance in actual job situations or experiences as close to reality as possible. During this period of training, the patient may continue to receive services from the medical unit, the social adjustment unit, or any other part of the rehabilitation center. (See Fig. 17.)

Differences in disabilities and the nature of the community will dictate differences in the kind of training program to be employed. In addition to working with local industry, the local training resources will supplement the center's training programs whenever practicable and suitable. Trade schools may accept only the more capable candidates who do not have emotional or medical problems, and in some cases, they may not be able to give the personal attention needed. The rehabilitation center deals with complex problems and disabilities; therefore, its vocational training unit will need to give greater emphasis to limited training objectives which are often more suitable to the restricted educational and cultural backgrounds of many of its patients.

Training in a range of vocations should be offered to accommodate several levels of abilities, skills, and interests. In addition, the changing personnel needs of industry make a representative range important.

There follows a sampling of some of the vocational training fields that the architect may be called upon to plan for:

1. Commercial
 2. Tailoring
 3. Drafting
 4. Watch repair
 5. Shoe repair
 6. Furniture repair and upholstery
 7. Machine shop operation
 8. Radio, television, and appliance repair
- (See Fig. 18.)

Sheltered Workshop

The sheltered workshop provides additional opportunities for further evaluation, training, and eventual employment of the handicapped individual. The sheltered workshop was once thought of as a place for terminal employment of those who could not benefit from further training. Today this concept has changed, and it is established as one of the steps in the rehabilitation process. There will, perhaps, always be some patients who, because of extensive or complicated disabilities, require the environment of the sheltered workshop as the only means of permanent employment.

The sheltered workshop is never an isolated unit in terms of program, but is part of the total vocational area which in turn is an integral part of the center. For selected patients, it is the best means of developing work tolerance, work habits, confidence, and skill. It also provides a means for the development of industrial quantity standards. The added incentive of pay for work done is often the motivation needed to help the disabled person carry through his rehabilitation program. This work is most frequently secured from industry or other sources on subcontract basis.

This work must be done within the most businesslike atmosphere and framework, yet without undue pressures of time; however, it

must meet the standards of quality and guarantee delivery of the required quantities on time schedules. It must provide payment for services rendered and rewards in terms of individual growth and development.

Location Within Building The sheltered workshop should be conveniently related to the other areas of vocational services. It may be a detached or semidetached unit with a separate patient entrance, as patients engaged in the shop usually work an eight-hour-day program and no longer require the intensive services of the medical department.

Depending upon its closeness to the medical department of the center, the shop may require a first-aid room. In the larger workshop a full-time nurse may be required.

As work within the shop may be noisy, separation from quiet areas in the center is recommended.

For delivery and shipment of goods, it is essential that the unit be adjacent to a loading area.

Organization of Space This area will closely resemble industrial space and will house industrial operations. The heating, ventilating, and dust collection systems will need to be planned accordingly, with floors designed for adequate loads and an electrical system to meet many different kinds of demands.

The type of work carried out in the shop will be subject to frequent change. Flexibility in organizing the space is, therefore, essential: the area should have a high ceiling and be free of columns. Floors should be designed to take heavy loads of equipment and stacked materials. Much of the work under contract in the shop will be of an assembly line nature. However, the products may merely require work surfaces for their assembly or they may require special equipment (frequently supplied to the center by the contracting firm if it is for a particular job). In laying out equipment in the shop, it is advisable to obtain expert industrial advice in order to assure efficient flow patterns and simplified handling and storage of materials and products.

Some work surfaces should be adjustable in height and all should be designed for the use of wheelchair patients.

Electrical power outlets should be frequently spotted along bench walls and/or the ceiling grid. Floor outlets for power tool use in the central area of the shop are recommended. Wiring should be sized to take a varying power demand.

Adequate general illumination should be provided with increased intensity at work stations as dictated by the task.

A time clock for the patients' use is sometimes provided in the workshop to encourage punctuality and to determine the patients' production rate.

All necessary safety precautions should be taken to protect the patient from power tool hazards, fire hazards, falls, and other mishaps. A potential hazard exists when there is insufficient space for the storage of materials and products. Ample storage space should be provided for the orderly, safe arrangement of bulky items. A sprinkler system installed in the shop will reduce fire risk.

Storage is a major problem and is related to the volume of items handled. The space for storage will vary from 15 percent to 50 percent of the work area.

Receiving, shipping, and handling of bulk items require additional space. This space

REHABILITATION CENTERS

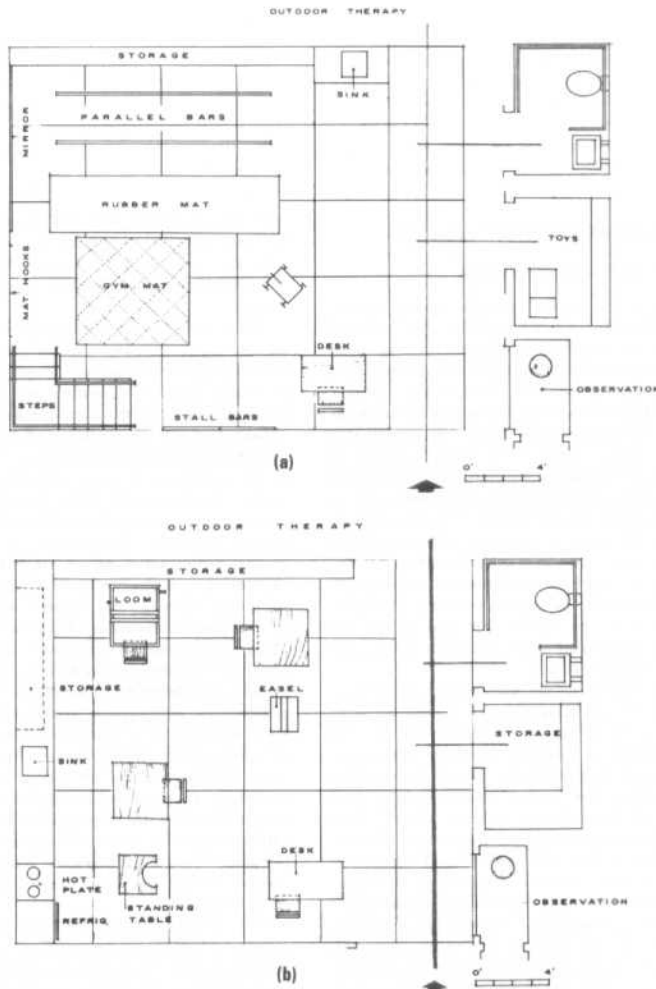

Fig. 19 (a) Children's physical therapy. (b) Children's occupational therapy.

should be related to a loading dock and truck service area. The service area should be planned so that it does not interfere with other vehicular or pedestrian circulation.

As patients working in the shop will usually work an eight-hour day, facilities for their comfort should not be overlooked. If the center has no dining facilities, a lunchroom convenient to the shop is recommended, as some patients will bring their lunches with them. Provision of a cafeteria is also considered a desirable facility where the number of patients warrants it.

Most states have specific requirements for rest areas for men and women. These requirements should be checked carefully before planning lounges, toilet facilities, and lockers for the patients in the workshop.

A small office for the workshop supervisor should be provided, and so designed that there is maximum supervision of the shop activity from the office. Additional office space will be required for records, cost accounting, and estimating. The size of this area will be determined essentially by the volume of work and number of contracts handled by the workshop.

Physical Therapy Exercise Room The requirements here are similar to those needed in the exercise room for adults, except that the equipment is selected for the child's size and interests. (See Fig. 19.)

The space indicates a minimum exercise area staffed by one therapist.

Treatment cubicle requirements are the same for children as adults; equip them with treatment tables and ceiling-mounted mirrors above.

Relate the area to outdoor therapy for outdoor exercises.

Provide a sink for the therapist's and children's use.

Toilet facilities for children should be immediately convenient to the exercise room and outdoor therapy.

Special equipment may have to be designed for individual cases. Figure 19 illustrates a movable stall bar and parallel bars adjustable in height and width for children of varying ages.

Occupational Therapy Equipment should be selected for the child's physical and mental age level. The plan indicates an area staffed by one therapist.

Place toilet facilities convenient to the therapy room.

Relate the room to the outdoors so that some activities may be conducted outside.

Although special equipment may be required for individual cases, equipment indicated includes standing tables, typing tables, work tables (all with adjustable heights), loom, easel, and workbench.

Provide a sink within the room for the children's and therapist's use.

As training in eating may form a part of the

program, facilities for snacks—refrigerator, hot plate, and sink—are indicated. Or locate this facility within the children's treatment and training area to serve the nursery as well as the occupational therapy room.

Exterior circulation involves both vehicular and pedestrian traffic. Buses, taxis, automobiles, and service trucks must be considered. *Parking spaces* should be located so that neither patients nor visitors need cross drive-ways to enter the building. Separate areas of the parking space should be designated for patient, staff, and visitor use. Appropriate directional signs should be considered for the efficient control of traffic. In some centers where many outpatients drive their own cars, a carport designed for wheelchair patients is a considerable convenience. (See Fig. 20.)

All centers will require a *service area* for the delivery of equipment, supplies, and fuel. However, centers with kitchen facilities, vocational training programs, and a sheltered workshop will have a greatly increased service problem; and the service area and its relation to other traffic must be studied accordingly.

Adequate *maintenance shop* facilities are essential. The shop not only will serve general maintenance purposes, but frequently will be used for the repair, modification, or fabrication of furniture and equipment used in the center.

Fig. 20 Parking space for cars operated by disabled persons.

The Physical Plant

The physical plant shall provide a safe and sanitary environment with adequate diagnostic and therapeutic resources.

The design and construction of the physical plant should be appropriate to the type of services it houses, to the staffing and organizational pattern of the facility, and to local geography and style. It will, therefore, be unique for each facility, but it must be safe and must make a positive contribution to the efficient attainment of the facility's goals. It must satisfy the physiological as well as the psychological needs of patients and staff.

Sleeping units for patients are designed to promote comfort and dignity and to ensure privacy consistent with the patients' welfare. In the absence of other state or local requirements, there is a minimum of 80 sq ft of floor space in single rooms and 70 sq ft of floor space per person in multiple patient rooms. It is desirable that multiple patient rooms be designed to accommodate no more than six patients, but preferably four. There may be a need for appropriate security measures incorporated into the physical design of some wards.

There is a minimum of one lavatory for each six patients, one toilet for each eight patients, one tub or shower for each fifteen patients, and one drinking fountain on each ward. A lavatory is installed in each toilet area. Appropriate provisions are made to ensure privacy in toilet and bathing areas.

Since psychiatric patients are generally ambulatory and need to associate with other patients and with staff, there is provision for day rooms and recreational areas. At least 40 sq ft of floor space per patient is required for dayrooms. There are also usually solariums, a dining room or cafeteria where many patients take their meals, a visitors' room, a gymnasium, an exercise area in the building or perhaps on the grounds, and rooms for special treatment, interviewing of patients, group and individual therapy, etc. Other facilities for patients might include a locker room or individual lockers in the sleeping units, a small laundry room, a snack kitchen on each ward, and a coffee shop, clothing shop, and cosmetic shop for patients as well as employees.

Offices are provided for physicians, psychologists, social workers, nursing administrators, dietitian, and other staff members, and these are conveniently located to encourage effective communication with patients and other staff. Nurses' stations should be centrally located to permit full view of recreation areas and immediate access to patients and to treatment areas. Appropriate conference rooms are also provided, and there are suitable arrangements for clerical staff for each department or unit.

Standards for Psychiatric Facilities, The American Psychiatric Association, Washington, D.C., 1969.

SIX TYPES OF PSYCHIATRIC FACILITIES

Community Mental Health Centers

The community mental health center represents the formal reflection of the professional objectives of providing comprehensive services and continuity of care for the prevention, early detection, treatment, and follow-up care of mental disorder within a designated population. The comprehensive center is essentially a program rather than a building complex; it is a program that seeks to plan and coordinate the range of mental health services required to meet the mental health needs of a population. It is a combination of services either under a single administration in a discrete physical entity, under a single administration in multiple physical facilities, or under various administrations which, by contracts and/or agreements, are organized to provide the continuity of services noted above.

A center may be under governmental, philanthropic, or private auspices, or it may be supported by a combination of resources. If it is to be an effective agency, however, the community served by the center should participate in establishing the major needs, goals, and priorities of the mental health center. The community and the staff of the mental health center must define the goals and establish a priority system for the attainment of these goals. The community is ultimately responsible for identifying resources and needs, obtaining sufficient financial support to assure adequate numbers of competent personnel, adequately paid and given an adequate physical plant to implement the programs to achieve the stated goals.

As a minimum, the center must provide outpatient, inpatient, partial hospitalization (including day care) services, community consultation and professional education for other than the staff of the center, and clinical diagnosis and treatment on an emergency basis. It is also desirable that it participate in public education to promote or conserve mental health research to increase the body of knowledge about mental illness and the effectiveness of services utilized, home care and follow-up, nursing home care, vocational rehabilitation, guidance for the families of emotionally disturbed persons, and otherwise contribute to maintaining the optimal functioning of individuals with residual sequelae or complications of mental disorders. Services of the center should be easily accessible and widely publicized to the community served.

To provide comprehensive services and continuity of care, the community mental health center should have easy relationships with other "people-serving" agencies, and particularly with the public psychiatric hospital serving the area. Patient care must be coordinated between the center and other agencies, and patients must move from one element of service to another within the center with ease, as treatment needs indicate. For example, in mental health centers that are part of or closely related to general hospitals, the necessary inpatient, dietetic, laboratory, pharmacy, medi-

cal, and surgical services might be provided by the general hospital. Arrangements need only be made to ensure availability and ready accessibility for patients in the mental health center.

To be truly comprehensive, the mental health center must be responsible for the adequacy of services provided to persons with special problem mental disorders or to populations facing unusually chronic and severe emotional stress and who are alienated from their community or the broader community's supportive social systems. It may not be feasible for the center to provide all of the clinical services necessary in managing the difficult biological and social problems presented by drug dependency, alcoholism, aging, delinquency, mental retardation, or the many other special problems included among the mental disorders or in which mental disorder is suspected of playing a significant part. The center should, however, identify the population at risk for each of the special problems and plan a program to provide preventive, diagnostic, therapeutic, rehabilitative, or supportive services for each of these populations. It should identify the community's most likely agents for early intervention to assist or support individuals in each of these populations or identify agents who are providing therapeutic and rehabilitative care. The program should indicate the ways in which the center would be most useful to these community agents.

The responsibility for the mental health needs of a population implies that the mental health center should help various social systems of the community function in ways that develop and sustain effectiveness of individuals participating in these systems. The center should aid these systems in their support of persons with mental disorder. The implications for prevention, diagnosis, treatment, and rehabilitation are obvious; the recipient of mental health services includes the patient but the services extend to his family and to a variety of social systems. Consultation and education in the community are important functions of any center. In these ways the center responds to the community's need for interlocking, strengthening, and expansion of all its resources that have a bearing on mental health. Community consultation and education offer possibilities for influencing mental health beyond the confines of hospitals and offices and thus contribute to the prevention of mental disorder.

To deliver this broad range of services, a flexible organization with a multidisciplinary staff is required. In addition to the usual professional staff of psychiatrists, psychologists, social workers, nurses, and activity therapists, there may be a variety of nonprofessional personnel, volunteers, and social scientists to add new perspectives to the center. Staff may be organized by services (prevention, diagnosis, intensive treatment, extended treatment, rehabilitation, etc.), by programs for specific population groups (children, adolescents, the aged, alcoholics, mentally retarded, etc.), or by geographic areas of the community served. Regardless of the organization, there

must be adequate qualified leadership, administrative and clinical, to assure thoughtful supervision, planning, evaluation, and coordination required to blend the array of available talents and resources into an effective center of services.

Responsibility and commensurate authority should be delegated to ensure optimal utilization of each person's skills, respecting principles of ultimate legal and clinical responsibility. As stated elsewhere by the APA, "The need for cooperatively defining the area of activity and responsibility for professionals who participate in the care of patients requires that physicians or their designees be recognized as having the ultimate responsibility for patient care. They, and they alone, are trained to assume this responsibility. In the public interest, other professionals or nonprofessionals, when contributing to patient care, must recognize and respect this ultimate responsibility."¹

Psychiatric Outpatient Clinics

In a psychiatric outpatient clinic, a psychiatrist assumes responsibility for providing diagnostic, consulting, and therapeutic services for outpatients with the help of a professional staff that includes at least the disciplines of psychiatry, psychology, and social work. This staff nucleus may be supplemented as needed by representatives of related disciplines, such as pediatrics, internal medicine, neurology, mental health nursing, speech therapy, remedial techniques, physical and occupational therapy, and rehabilitation.

Members of the various disciplines not only work on the staff but also function on the team in daily practice, coordinating their skills to meet the needs of patients. The psychiatrist who serves as director sees that this coordination is effective. He assumes responsibility for all clinical functions and is on duty sufficient time, on a regularly scheduled basis, to adequately discharge his responsibility. He assures adequate evaluation of all new patients, supervision of the staff, and sustained direction of the total program of services. The psychiatrist-in-charge retains overall authority, but may delegate administrative, as distinct from clinical, responsibility to a nonmedical executive or administrator.

In addition to diagnosing and treating patients, the clinic provides training for professional psychiatric personnel and those of other disciplines as well as education for the public; it participates in various community endeavors related to the mentally ill and carries out research. The methods of implementation and the proportionate emphasis given to the various functions differ according to local circumstances, community needs, and clinic policy.

The clinic may serve patients for whom appropriate psychiatric assistance in a convenient outpatient clinic may prevent more prolonged illness, those recovering from a stage of illness that required hospitalization and who may need further outpatient care as they resume a regular way of life, those who are referred for prehospitalization evaluation, and those who can benefit from temporary therapeutic intervention to overcome a life crisis.

Admission policies for outpatient clinics vary. Many clinics have an "open door," or "walk-in," policy, indicating that they accept both self-referrals and referrals from community agents. Others accept only those cases that have been referred by another professional source. Some clinics specialize in the diagnosis and treatment of children, adults, or special populations, such as people with alcohol problems. Each clinic has a written plan indicating the scope of its admission policy and referral plan, and the plan is well known to all referring sources.

The services of a clinic may be offered on either a full- or part-time basis, according to local circumstances. Whatever its arrangement, the clinic should be accessible to the members of the community it serves. For example, a clinic serving an area where many working people are paid by the day or hour with little or no provision for sick leave should be open some evenings or weekends so as not to discourage or penalize those who would have to take a loss in pay to begin or continue treatment.

The clinic's participation in community service plans is an important responsibility. Some individuals may have a problem that can best be removed or alleviated by another agency, and the clinic cooperates with other community resources wherever possible. Some patients need help from several sources, and the professionals involved must clarify the needs and outline areas in which each can be most effective. Working relationships with surrounding inpatient facilities are maintained to achieve easy flow of patients in and out of inpatient services and to avoid administrative delays and failure of communication about patients.

The clinic may be affiliated with a medical school, hospital, welfare or public health department, or other appropriate professional organizations for the exchange of services, scientific advancement, and professional and administrative support. If not, it achieves these aims through the use of qualified consultants or by establishing a professional advisory board of appropriately qualified persons.

The psychiatric outpatient clinic is often asked to furnish an evaluative report regarding a patient. The content of a report is determined by the purposes of the agency for which it is prepared and it is in keeping with ethical practice.

Psychiatric Services in General Hospitals

All general hospitals should have a well-known plan for receiving, management, and disposition of psychiatric patients. If the general hospital has a psychiatric service or department, there must be a qualified psychiatrist in charge, with appropriate allied personnel, particularly nursing personnel who have had training in the management of psychiatric patients.

Every general hospital must think through its responsibilities for the person presenting himself with psychiatric symptoms, in order either to admit the patient or to assist in quickly referring him to the nearest treatment resource capable of providing prompt diagnosis and treatment for the particular case. The feasibility of establishing a psychiatric service in a general hospital as a part of the network of the total community health program will depend upon many factors, including local needs, the availability of other facilities, the availability of staff, and the orientation of the medical professional in the hospital and community.

Whether a separate psychiatric service can or cannot be provided, it is frequently possible to use some general medical, minimal care, or other beds for psychiatric patients and to secure the services of a consultant psychiatrist. All good general hospitals have a plan for handling psychiatric emergencies, such as acute toxic reactions, suicide attempts, and acute behavioral disturbances. Small hospitals may have two or more rooms for such patients, pending their transfer to a hospital where special psychiatric facilities are available. It is advisable that no patient with suicidal tendencies be released without psychiatric consultation if a psychiatrist is available.

When the general hospital has a psychiatric service, the service provides for the care and treatment of patients admitted for psychiatric disorders and also for those patients who, in the course of hospitalization for another reason, experience a psychiatric illness. Most patients are admitted voluntarily, although occasionally the hospital seeks legal authority for detaining one who is very disturbed. Any limitations on admissions, such as those imposed by the physical construction of the unit or by the training and experience of its staff, are clearly stated in the plan of the hospital.

Because of the small size of the psychiatric unit in most general hospitals, the unit usually focuses on intensive short-term therapy and diagnostic services. Some general hospitals have, however, found it possible to develop suitable facilities and staffing to admit and treat psychiatric patients who are expected to remain over 30 days. Some hospitals also have provision for partial hospitalization, in addition to round-the-clock services, and for outpatient services to former patients and others who do not need full-time hospitalization.

Experience has indicated that, expressed as a percentage of the bed capacity of the hospital, the number of psychiatric beds required will vary from 3 to 15 percent, the most usual figure being about 10 percent of the total beds. A capacity of 20 to 26 beds in one nursing unit seems to be most efficient. When a hospital is capable of supporting more than this number of beds, they are usually provided in two or more nursing units. Experience has shown that men and women may be treated in one unit if adequate facilities are available.

Since the psychiatric service operates as an integral part of the hospital, many of its functional services are provided by the hospital administration. These might include most of the general professional services: i.e., medical, surgical, and dental; dietetic, laboratory, x-ray, pharmacy, library, chaplaincy, and medical records; and administrative and maintenance services.

Private Psychiatric Hospitals

Private psychiatric hospitals are nongovernmental specialty hospitals. Like general hospitals, they may be operated on either a nonprofit or for-profit basis. They have the responsibility of providing treatment programs with definitive goals for the welfare of the patient, with the realization that the period of hospitalization may be only a segment of the total treatment plan.

The medical staff should make use of the opportunity provided by a high ratio of medical staff to patients to regulate the therapeutic program and to observe the processes of illness and the response to therapy. The most advanced approaches to treatment, and individualization of program to meet each patient's

¹ *Principles Underlying Interdisciplinary Relations Between the Professions of Psychiatry and Psychology—A Position Statement* by the Council of the American Psychiatric Association, February 1964.

MENTAL HEALTH CENTERS

needs, should be employed. The hospital should take advantage of around-the-clock observations by many trained observers, and multidisciplinary views in conference, in the evaluation of therapy and the integration of theory and practice. There should be a periodic evaluation of the effectiveness of the hospital therapeutic program. Although the primary function of the hospital is to maintain excellence in psychiatric treatment, the professional and administrative staff should be encouraged to utilize the unique opportunities for education and research.

Most private psychiatric hospitals serve their geographic communities—local, state, and regional—although a number of them, because of their special or unique treatment programs for specific categories of patients, receive referrals from wherever in the world these patients come.

Private psychiatric hospitals, therefore, vary greatly. Each follows the program determined by its medical staff, its approach to treatment and its goals. Each private psychiatric hospital must have established written procedures by which it will either admit a patient or quickly refer him to the nearest, most appropriate, treatment facility. A qualified psychiatrist must be responsible for the treatment of the patient, and there must be other mental health professionals, including nursing personnel with training in psychiatric nursing.

The length of stay in a private psychiatric hospital should be commensurate with the goals of therapy and the patient's illness. In keeping with the current concepts that early and effective intervention may result in the return of the patient to his community after a very short period of hospitalization, the average length of stay is less than 60 days in three-fourths of the private psychiatric hospitals. To meet the ultimate needs of the patient, many hospitals maintain medium- or long-term intensive treatment programs as well. The primary goal of hospital treatment is not the shortest possible stay but the most effective therapy. Within the limits of therapeutic goals, the hospital should provide the type and amount of treatment that will result in the patient's resumption of healthy functioning.

Public Psychiatric Hospitals

A public psychiatric hospital is defined as an institution provided by the community—whether city, county, state, provincial, or federal government—for the diagnosis, treatment, and care of patients with psychiatric and neurological disorders. Most hospitals in this group are state or provincial hospitals. They provide both short-term and long-term treatment and admit patients both voluntarily and by legal commitment.

While it is recognized that variations in the usual type of state hospital organization are suitable in certain localities, the essential professional, diagnostic, treatment, and administrative and maintenance services described in the preceding section on general standards can be applied to all public hospitals by individual interpretation. Each public hospital has an important function to perform in providing necessary psychiatric services to its community and in promoting psychiatric education and research. Recognizing the advantages of affiliation with medical schools and other medical centers in their areas, many public hospitals have established formal programs of participation in cooperative educational and research efforts.

Whether the total treatment program of the

hospital is separated into discrete units depends upon its size, its type of organization, and the medical administrative philosophy. However, patients have individual and differing needs, and the treatment program, however administratively organized, seeks to serve these various needs.

The hospital should be large enough to meet the community's needs for psychiatric services, but not so large as to compromise its ability to meet the needs of each patient for individual treatment. Optimal size might be described as the most efficient and effective balance between the facility's ability to meet the unique needs of the community and its ability to meet the unique needs of each patient. One method that has been devised to achieve this balance is the unit system.

Larger hospitals may operate under this system, with several semiautonomous patient care units making up the complex. The treatment programs are organized into separate units of similar size, staffing, and types of patients. Regardless of how long he stays, each patient is admitted, treated, and discharged within the same unit. His treatment is the responsibility of the same group of staff members from admission to discharge and aftercare. In some instances, the units represent specific geographical areas; this enables the professional staff to work closely and continuously with professional and lay community agencies from that region. Other facilities do not find this geographic admission plan practical and prefer to admit patients to each unit in rotation. Regardless of how admissions are handled, the goal of each unit is appropriate treatment for each patient at the most appropriate site.

The treatment program may include separate wards for certain types of patients with special treatment, educational, and rehabilitation needs, such as children, adolescents, alcoholics, patients with tuberculosis, and others who require intensive medical treatment in addition to psychiatric care.

Increasingly, public hospitals are following the mental health center concepts of comprehensiveness of service and continuity of care. They are, therefore, developing a range of services, including programs of varying degrees of partial hospitalization, outpatient services, rehabilitation, vocational guidance, and aftercare in addition to the intensive inpatient treatment programs. A proper balance of these other programs allows for the more efficient use of the inpatient services.

The concept of the "open door" has been applied to the majority of wards in most psychiatric hospitals. The open hospital encourages early treatment by emphasizing the voluntary nature of hospitalization and the expressed confidence of the staff that the patient can accept responsibility for his own management. Freedom of movement enables patients to do many things for themselves that might have to be done by staff members under other conditions, and thus allows more staff time available for the promotion of active treatment. It is necessary for some facilities to maintain a closed ward or wards, however, for those patients who may be likely to endanger the safety and welfare of themselves and/or others. Confidence in the facility can best be maintained if appropriate precautions are taken to protect the community from the exceptional patient who has in the past caused it concern.

The hospital encourages and participates in community planning for the development of appropriate alternative resources and facilities to deal with social problems that have in the

past often been assigned to the public psychiatric hospital due to the lack of available alternatives. The most appropriate and efficient use of scarce psychiatric resources requires that all possibilities for securing the best treatment and care for each individual patient be explored by the patient's family, the family physician, and community social agencies, and that a broad range of resources be available in the community to meet the multiplicity of needs.

The hospital encourages community provision for diagnostic, treatment, rehabilitation, and educational and preventive mental hygiene services for former patients, and for those for whom hospitalization may be averted, to ensure a comprehensive network of mental health care services. Within this network some services may be provided by the hospital's mental health clinic, which functions on a regular, scheduled basis, either in a fixed location or on a traveling basis. The clinic assists in the rehabilitation of former hospital patients, advises those about to enter the hospital, offers treatment to those who do not need hospitalization, and diagnoses and/or treats children with behavioral or educational problems. The staff of the clinic includes as a minimum a psychiatrist, a social worker, and a psychologist, and, if the hospital has adopted the unit system, the same team follows the patient from pre-admission interview to discharge and follow-up care. The services of the clinic also include follow-up counseling, evaluation of adjustment after discharge, and medical supervision of drug dosage.

Services for the Mentally Retarded

The past ten years or more have brought about a dramatic change of basic concepts regarding the care and treatment of persons with the mental retardation syndrome. Consequently, requirements of care and treatment have shifted to an extent that the newly developed or developing facilities can no longer be considered as one compatible group of "hospitals and schools for mental defectives" as was the case in earlier years.

First of all, the care, treatment, education and training of mentally retarded persons in the low borderline and educable range have shifted significantly from residential facilities to day schools. Trained or qualified educators along with other specialists (medicine, audiology, speech, and physical therapy) provide meaningful and adequate services within the public school system or in schools operated by affiliates of the National Association for Retarded Children.

Secondly, the care, treatment, and training for more severely retarded children (trainables) are being provided in many communities in a manner similar to that in which these services are rendered for the youngsters who are educable.

As a third observation, it must be acknowledged that, for some years now, there has been an observable trend for those persons who suffer from the rather severe to severest degrees of retardation (decrebrate syndrome) to outnumber either the educable or the trainable retardates in state institutions. Their demand upon the availability of total lifelong care has become a dominant factor.

Thus, it is no longer possible to establish meaningful standards based upon traditional concepts. A new approach is indicated that takes into consideration factual changes and continued transition.

The complexities of needed services can best

MENTAL HEALTH CENTERS

be dealt with by projecting various life-span requirements as known to us. However, we shall not attempt to make specific recommendations for those services that are non-medical in nature.

The Infant and Small Child Most mentally retarded children are retarded at birth (prenatal and perinatal retardation), although it may not be evident at the time. They require diagnostic, prognostic, and treatment services.

The pre-school-age medical clinic may operate as an independent agency, a part of a general hospital, or a part of the state hospital-training school system. In any event, utilization of existing services and efforts at integration in regional areas will be made and standards must be established and maintained to meet existing needs.

It is desirable that the director of the clinic be a well-qualified pediatrician. He will have medical consultants on his staff (neurologist, child psychiatrist, ophthalmologist, dentist, physiatrist, nutritionists, public health nurses, and others as needed). Essential are full-time or part-time qualified social workers, clinical or developmental psychologists, audiologists, speech, occupational, and physical therapists and medical secretaries. The number of staff employed must correspond to the needs of the patients referred to the clinic.

The clinic must have adequate space to function. It must have available all diagnostic tools and procedures that are necessary to establish an inclusive and comprehensive diagnosis, such as roentgenology, clinical and anatomic pathology, biochemistry, genetics, and electroencephalography.

All personnel must meet licensing and/or certification requirements of their respective professions. The clinic, if it is eligible, must meet the standards of the Joint Commission on Accreditation of Hospitals.

The Younger School-Age Child Mentally retarded children, once properly diagnosed, will re-

quire a broad range of varying services:

Children who are ambulatory and without significant adjustment problems are, generally, entered into nursery schools with subsequent promotion into subprimary and appropriate grades of the public school system. State licensing procedures establish necessary standards for personnel and facilities.

Children who are not ambulatory or who have major adjustment problems that cannot be dealt with in the public school system or the private home may require in-residence facilities that provide special orthopedic or psychiatric services or services to the blind, deaf, or others. All children in this category will be given the required additional diagnostic, treatment, rehabilitative, and educational services that are needed to assist them to develop their optimal potential. Such programs must be multidisciplinary, under qualified medical direction. Thus, they must meet the requirements of the Joint Commission on Accreditation of Hospitals.

As the process of treatment and rehabilitation progresses, a differentiation of each child's long-range needs will become evident. It may lead to discharge into the community and referral to a child guidance clinic and to the public special school system. It may require prolonged hospitalization because of specific medical requirements. Or, it may result in providing lifelong protective care in an accredited institution for the chronically ill (extended care unit), a licensed nursing home, or a licensed boarding home. In any event, local, state, and/or federal licensing requirements must be met and the facility should be accredited by the Joint Commission on Accreditation of Hospitals if it is eligible.

The Progressing Preadolescents and Adolescents Most of the mentally retarded youngsters in the educational and training programs will reach the limit of their academic potential before the age of sixteen. Therefore, it is necessary that meaningful and adequate prevoca-

tional programs be available at the appropriate time. Whether such a program is part of a public school system or an integral part of a private or public residential care facility, it must meet the licensing and certification requirements of the state and/or federal government. Under the current legal definition, a mentally retarded youngster capable of rehabilitation, as interpreted by the Division of Vocational Rehabilitation, qualifies at age sixteen to participate in this program.

Adequate day care programs and/or domiciliary facilities must meet the program needs of the clients. Also, they must meet licensing or certification requirements of each licensing body (department of health, department of labor, department of education, the fire marshal, department of insurance, etc.).

The Young Adult and the Adult By the time a retarded person is eighteen years of age, his future role in our society can be assessed fairly accurately, in most instances. The need may range from living more or less independently in the community or in a supervised group-living program (hostel, sheltered workshop) to residence in a licensed boarding home, a licensed nursing home, or in an institution for chronically disabled or ill persons. Correspondingly, he may be economically independent, partially self-supporting, or receive public support through Medicare, Medicaid, Social Security, or aid to the permanently and totally disabled.

In any event, adequate legal and social provisions must be made to protect the person with the mental retardation syndrome against physical, emotional, social, or economic exploitation and abuse. Also, regardless of where the retarded adult lives, he must have adequate access to all community resources that he may need at any given time in his life span. This will require programmed supervisory services that can be included in an adequate protective mechanism (Guardianship Act).

MENTAL HEALTH CENTERS

SPATIAL NEEDS OF PROGRAM ELEMENTS

NOTE: Design of all spaces should be noninstitutional. The following are suggestions for consideration in all program element needs indicated below:

- Openers in space-planning
- Live plants
- Design for groupings of 4 to 8 persons
- Comfortable light level (natural light, desk lamps, incandescents instead of neon, etc.)
- Freedom for hanging pictures
- Warm surface finishes in natural materials
- Views outside
- Contact with outdoors
- Visual access to mainstream of activity.

The following does not assume that all services must be located under one roof (see Location of Services).

1. Inpatient Unit

This is a short-term residential facility for living under a supervised therapeutic program, requiring a domestic or college-dormitory rather than a hospital atmosphere. Architectural Section, NIMH, recommends this area be classified residential occupancy (NFPA No. 101) where permitted by local authorities.

Patient Needs

- Privacy for sleeping, dressing, and bathing.
- Provision for personal grooming needs.
- As few regulations for use of facility as possible.
- Patients should be able to rearrange furniture, hang pictures on wall, etc.
- Patient belongings should not be out of reach—lockable storage space should be provided in each patient's bedroom unless specifically prohibited by program.

Domestic Needs to Be Provided Laundry and snack kitchen for use by each living group (16–24 patients).

Socialization Areas A variety of settings is necessary:

- Space for small conversational groupings or quiet individual use (2–4 persons). Example: small living space in a suite of two or four bedrooms.
- Activity spaces for games, dancing, music, group living (16–24 persons). Two living areas are desirable to allow noisy and quiet activities to occur simultaneously. Quiet activity space could also be used for group therapy. Example: a large living room as the focus of living group activities with a smaller, comfortably furnished lounge adjacent.

Visiting Area Space should be provided for private visiting with family and friends. Example: an out-of-the-way alcove for 6 persons, located near the entrance to the unit and the nurse's station, allowing visual and conversation level acoustical privacy.

NOTE: each group of 16–24 patients requires the above spaces. Design should allow natural groupings of 4–8 persons.

Physical Planning Guidelines for Community Mental Health Centers, Clyde H. Dorsett, AIA, Architectural Consultant, National Institute of Mental Health, Bethesda, Md., 1978.

Recreation—physical exercise Space in the form of an exercise room, gymnasium, or outdoor space (especially in warm climates) should be provided. Example: small exercise room for group setting-up exercise program with agreement to use high school gym and playing fields located within easy walking distance.

Staff needs

- Lounge area
- Storage for personal property
- Staff toilet
- Area for charting/private discussion with therapists
- Security for drugs
- Multiuse patient interview space, family discussion, etc.
- Minimal barriers to interaction with patients. Example: desks are preferable to glazed nursing stations.

Housekeeping Needs

- Domestic housekeeping:
 - Linens—in patients' bedrooms or locate for central distribution
 - Each bedroom unit to have own linen supply
 - Bathroom and personal items
 - Central janitor's closet
- Dietary services:
 - Snacks, patients' activities in kitchen
 - Feeding—hospital cafeteria and kitchen service on units; storage for dishes, linens, etc.
 - Icemakers
 - Complete domestic kitchen—exhaust system must be adequate

Intensive care

- Acoustical privacy
 - Social space for contact with staff and freedom to leave confined room
 - Close supervision by staff
 - Controlled access to toilet, wardrobe, light switches outside patient's room
 - Security
 - Tamperproof equipment and fixtures within patient's room and toilet (but not obviously tamperproof to patient)
 - Tempered plate glass or removable-type detention screens
 - Treatment room—first aid, emergency physical examination items for special programs such as drugs, alcohol, etc.
 - Laboratory with storage
 - Direct access from nurse's station and from emergency rooms in general hospitals
 - Audio communications between nurse's station and patient's room
 - Patient rooms may be used for medical care when needed.
 - Necessary equipment not removable from the room must be lockable and concealable.
- We recommend occupancy for this area be institutional.

2. Emergencies

Emergency can occur in any element of service at any time. Most common:

1. walk-in
2. escorted emergency

Walk-in: arriving at any element of service for the first time to get help. This person may come in alone or with others. He [or she] is ambulant and functioning.

Escorted emergency: ambulant but not functioning.

Physical Space for Walk-in:

- Inviting entrance
- Must have immediate relationship to outside while patient is in waiting-reception area
- Privacy with receptionist in stating his [her] needs

NOTE: all spaces for walk-in interview and initial treatment, admitting of walk-in emergency can be those used by outpatients.

Escorted emergency

- Will utilize all staff and space in emergency suite of general hospital.
- Additional spaces may be needed in general hospital emergency.

Space:

- Interview space that promotes communication between patient and physician.
- Holding space—waiting bed space—for patient to wait while disposition for treatment is considered (i.e., sedated patient).
- Entrance available directly to intensive care area for escorted emergencies.

NOTE: design and location should motivate interaction and communication between all agencies and elements of service utilizing the facility.

3. Outpatient

Admitting Offices Should be convenient to receptionist

Ancillary Services

- Waiting areas
- Secretarial space
- Public and staff toilets, lounge (coffee, sink, refrigerator), and library-workroom

Waiting Areas

- Limited to 8–12 patients
- Distributed throughout office areas
- Receptionist by front door—open, friendly, encourage contact between receptionist and patient

Office space	Conference and interview	Meetings (with consultation and educational service)
Play therapy	Group therapy*	Larger groups
Individual	Staff conferences	Community groups
Family	Interagency professional groups	General meetings

* Group therapy rooms to be utilized through total programs

MENTAL HEALTH CENTERS

Children's Treatment Adjacent to entrance and child therapist's office

Provide for observation

Provide for work sink (as part of "messy area"), and locked storage

Provide for separate toilet available to children; separate waiting area, with possibility of observation by parent; outdoor play space; scaled for children; cleanable surfaces

Office Space Should motivate communication between patient and therapist, should contain doctor (staff) and at least four or more patients and be flexible in arrangement of furniture.

Conference Spaces

Sufficient to accommodate 16 people

Suitable for audiovisual presentations, staff meetings, staff work area

Accessible to main entrance and/or office spaces and rest rooms

Suitable for group therapy

Provides storage closet

Staff Lounge Should be comfortable for 8 people adjacent to staff toilets, storage, and small kitchenette (coffee-making, lunch, refrigerator); also adjacent to staff library and workroom.

Need for large meeting room depends on availability of space in the community. Such a room needs audiovisual facilities, storage space, and sufficient toilet areas; it should be located between central facilities and community.

4. Partial Hospitalization

Day Care This requires a primary social area (living-room-type space)

1. Staff needs

Office space for day program director

Work area for staff

Medications

Nurses' lockers and toilet

(All located in position for information and control for particular hospital program)

2. Patient's needs

Storage for wraps and for personal articles

Telephone, drinking fountain

Toilets

Kitchen suitable for social groups and therapy

Occupational Therapy This consists of quiet and noisy activities and depends on the program. The most flexible design requires at least two rooms of classroom size with two kinds of storage: for patients' projects and materials and for equipment. The office for the program director is mostly program space for patient occupational therapy activities with the occupational therapist as part of the therapy team. It may be without staff offices and consist of large rooms divided by movable storage cabinets.

Recreational Therapy Social recreational therapy has the following requirements:

Large social space

Outdoor terrace for gardening, outdoor games, and an inactive outdoor area for quiet

T.V.—music

Quiet indoor space

Movies

Kitchen, canteen-type

Library (quiet)

Quiet social area

Not minimal but desirable are a swimming

pool with its own dressing rooms and toilets; and table games.

Structured recreational therapy programs require a small gym, for 8–12 patients at one time, with its own showers, dressing rooms, and lockers. One should inventory the community facilities that can be used: YMCA, schools, shopping centers, public parks, public pools, and other mental-health related programs in the community. An active outdoor area must be available with a playing field, large space for active games, etc.

The R.T. office can be same as for O.T. Weekend and night-evening program can be held within the same space as the inpatient program.

5. Children's Day Care

General needs include a staff office, a central reception room—gathering place, and classrooms. The program could utilize the adult gym. Toilets and a small snack kitchen should be available. (They could be used for other parts of the center's program.)

Classrooms need an area for messy (wet area) work (sink, etc.), an outdoor area, a teacher's work area with a desk (no desk in classroom), and also, for problem kids, quiet study; this class is separated from main classroom area by a curtain. Children's outdoor play space must be separated from adult outdoor areas.

6. Administration

Reception-waiting area

Director's office—meeting room nearby

Offices for program directors

Volunteers and part-time office and lounge—with lockers and toilets

Conference room

Library-workroom—staff lounge

Business—secretarial pool

Central records for all service elements

7. Consultation and Education

Meeting rooms and office spaces are located adjacent to or within central office groupings. Center can multiuse spaces for other elements of program for this purpose. (Basis of operations for C&S is out in the community and will use facility only to conduct business and for meetings.)

CIRCULATION

1. Use for Socialization

Circulation space can be used for more than transportation from one area to another. Informal contacts, pausing along the way to look at views, stopping for a cup of coffee at a coffee bar are activities that also encourage *social contact*.

Entry-Waiting Area Entrance through the front door to all program elements located in the facility should be possible. Arriving persons should be greeted by a staff person out in the open. Example: volunteer behind a desk located in sight of front door. Waiting areas should be small—groups of 4 to 6—in sight of receptionist. Waiting area allows view of mainstream of activity, but is located in well-defined area out of main traffic pattern.

Drinking fountain, toilets, and pay telephone are adjacent to entry-waiting area. A coffee pot is preferable to vending machines.

Contact with Staff Staff persons (volunteers, secretaries) should be located to be visible to persons moving in circulation pattern of building. Example: secretary for outpatient offices located in alcove with chairs for waiting adjacent to circulation space.

Provide informal social areas as part of circulation space leading to meeting rooms, partial hospitalization, etc. places where numbers of people congregate, and also at "nodes" in circulation system—places where people are likely to pause. Example: gathering space with area for coats, bathrooms outside community meeting room.

Waiting for outpatient appointments should be adjacent to outpatient staff offices. Director of Center should be located adjacent to other staff offices to encourage interstaff contact.

2. Orientation

Use of views outdoors and natural light—clear inside/outside circulation.

Clear relation of program spaces to front door: go here for outpatient, go there for day program, go around corner for inpatient. Privacy or separation provided by single turn in corridor or by screens—minimum of closed doors.

Staff person to greet arrival to program area—secretary for outpatient area, nurse or volunteer located by entrance to inpatient unit, etc.

Use staff and design of circulation space rather than barriers (locked doors) for control.

3. Time use

Locate community meeting areas near front door for night-time use—lock off rest of facility.

Partial hospitalization/inpatient section could have its own entrance for day/night use.

4. Variety

Circulation spaces should contrast light, dark, outside, inside, narrow, wide, free, controlled, stimulating (warm colors), subdued (cool colors) to provide clues to kind of activities associated with nearby program spaces and to maintain orientation. Example: corridor outside day program area widens to allow informal socialization and use of lockers located against one wall and is lit by skylight.

5. Zoning

Program elements should be related to:

Public accessibility

Acoustical separation

Heavy circulation/noisy activities

Quiet/private activities

Scheduled use/nonscheduled use

Frequency of use

Day/night use

Unique or common use

Sole staff use

Sole patient use

Joint use by staff and patients

Relation to other program spaces

Relation to front door

Need for outdoor space and natural light

Need for privacy/controlled access

NOTE: The prevalent dichotomy between circulation/service spaces and program spaces should be minimized where possible.

By WILLIAM BREGER, AIA

INTRODUCTION

Current thinking in health planning emphasizes the concept of providing a spectrum of care which serves the health needs of the entire community. This spectrum includes general medical and surgical facilities, mental, rehabilitation, and tuberculosis hospitals, and long-term care facilities, hereafter referred to as LTC, which provide care beyond acute, short-term medical and nursing care and may be in either chronic hospitals or nursing homes.

While the functions of a chronic hospital are relatively clear, what is understood by a nursing home can be somewhat ambiguous. For our purposes, an LTC may be defined as a facility which is operated either independently or in connection with a hospital and provides nursing care and medical services under the general direction of persons licensed to practice medicine or surgery. Furthermore, unlike the chronic hospital, the LTC generally does not have resident physicians and limits its medical services to minor treatment, diagnostic x-ray, and minor laboratory analysis. Although good medical practice should be available wherever and whenever a patient needs it, the fact is that major medical and surgical treatments are almost always performed in other facilities.

Eight categories of LTC facilities are readily identifiable: general hospitals with long-term-care beds, voluntary chronic hospitals, local government chronic hospitals, public home infirmaries, convalescent homes, voluntary nursing homes, proprietary nursing homes, and infirmaries or homes for the aged. Other nomenclature for the categories listed above are *extended care facilities*, *intermediate care facilities*, *shelter homes for the aged*, *geriatric homes for the aged*, and *long-term-care facilities*, homes for adults, foster homes, boarding homes, etc.

Each type has its own criteria for admission based for the most part on the type of care required; but reimbursement, whether through private payment, private medical insurance, Medicare or Medicaid, etc., may as well be a determining factor in patient placement. Whatever problems are involved, the fact is that patients often require a wide range of services beyond initial acute medical care, and these services may cross several "institutional lines," from intensive nursing and rehabilitative care through lesser degrees of nursing care to perhaps simply convalescent attention.

SOCIAL PLANNING CRITERIA

The basic criterion used in determining the needs for all health care facilities is the ratio of beds to the population served. Generally, we find that there are approximately 13.2 beds

per thousand population. A characteristic distribution of these beds is shown in Fig. 1.

Thus, the characteristic distribution of LTC in all categories is 4.8 beds per thousand, and, equally important, is the understanding that the most significant single characteristic of this patient population is that they are elderly. Their age characteristics are indicated in Fig. 2.

Fig. 1 Ratio of beds to population served.

Fig. 2 Age characteristics of patient population.

As Dr. Michael Miller says,¹ studies of this aging population in terms of their characteristics from a medical viewpoint have indicated that terminal cancer is seen in only 3 to 5 percent of the patient population. Varying degrees of organic brain syndrome, as manifested by memory, intellectual, and judgmental deficits associated with confusion and disorientation, with or without locomotion disability, constitute at least 70 to 75 percent of the patient population. Recent studies indicate that 20 to 30 percent of a nursing home population may be expected to have experienced a significant psychiatric decompensation in the pre-aged period. Of the whole, 40 to 50 percent will demonstrate significant cardio-renal-vascular disease in varying degrees of decompensation. Arthropathies are virtually a universal occurrence, although only 20 to 30 percent may

require specific management techniques. Fifteen to twenty percent of the patient population will present significant visual deficits, and there will be approximately the same number with auditory deficits. Other organ system involvement in the same patient is the rule rather than exception, such as gastrointestinal, pulmonary, neurological, and metabolic disorders. Multiorgan pathology in the chronically aged is a distinguishing characteristic of disability in contrast to other age groups.

The utilization rate differs as well. Extended care facilities, both independent and attached to general hospitals, have an average turnover of 7 to 8 patients per year per bed, or approximately 40 to 50 day stays, and there are less rapid turnovers for other LTC facilities (proprietary nursing homes, 1.17; voluntary nursing homes, 1.69; voluntary chronic hospitals, 1.30; public home infirmaries, 0.91; average of all LTC facilities, 1.43 per year).

One can conclude as well both from the demographic changes in a society that is proportionately growing elderly and the societal changes of placing the elderly members of society in medically oriented facilities that the LTC facility would have a greater percentage of beds allotted to it proportionately in the future and that this area of health concern would experience real as well as proportional growth.

Another aspect of social planning is the translation of social data into the architectural program. We have found that the ideal method of determining the physical facilities of the building is in terms of the proposed patient population rated by their capacities to perform activities, including daily living, both in terms of their physical capabilities and their behavioral capacities. Tables 1 to 4 describe the clinical nature of the patient population under study and give some index of the percentage of patient population in each group. At the conclusion, we will indicate the physical configuration of the nursing units that each group generates.

Group I—Physically Disabled (15–25 percent)²

Patients having significant physical disabilities but with emotional and intellectual intactness and the ability to socialize in an open, unsupervised environment. (See Fig. 3.)

Group II—Mentally and Physically Disabled (25–30 percent)

Patients with severe physical disabilities with superimposed substantial handicaps of organic brain disease, thus requiring total nursing care for physical disabilities and major supervision for social activities. (See Fig. 4.)

Group III—Custodial (15–25 percent)

Patients presenting moderate or no physical handicaps with either no or minimal emotional or social disabilities, thus able to function in an uncontrolled social milieu. However they

¹Hospital statistics from Health and Hospital Planning Council of Southern New York, 1970 and Long-Term Care, (LTC) Projection, 1973. Illustrations from Michael B. Miller and William N. Breger, "How to Plan for Extended Care Service," *Modern Hospital*, October 1966.

²"Synthesis of a Therapeutic Community for the Aged III," published in *Geriatrics*, vol. 21, pp. 151–163, August 1966.

²Based on 1,050 patient survey by W. Breger at Columbia School of Public Health and Hospital Administration, 1970.

function best in a professionally supervised environment. (See Fig. 5.)

Group IV—Mentally Disabled (30–50 percent)

Patients having minimal to mild physical disabilities with major emotional and social disabilities, who therefore require minimal nursing care on a purely physical level but because of the advanced degree of organic brain dis-

ease (senility) these patients are essentially totally and permanently disabled. (See Fig. 6.)

DESIGN CRITERIA

The design problems unique in this facility mainly involve the nursing units and supportive facilities that are required in terms of the projected patient population. The problems in-

herent in dietary, mechanical maintenance, and general and building storage facilities are fairly uniform regardless of the type of projected patient population and have a basic similarity to medical facilities of the same size, such as general hospitals, tuberculosis hospitals, etc. It should be noted that supply storage facilities, linens, equipment, etc., would depend to some extent on the projected patient population.

Fig. 3 Group 1, physically disabled. Symbols represent the following facilities: CR, community room; NS, nursing station; T, toilet; S, services (i.e., utility rooms, treatment, bathing, pantry, nonpatient storage); P, pantry; E, outdoor environment. (This list applies to Figs. 3–6.)

TABLE 1 Group I Facilities*

Area	Design requirements
Community room	Unsupervised
Physical therapy	Combined with community living
Exterior environment.	Unsupervised
Bedrooms	Sufficient area for wheelchairs, walkers, crutches; half of rooms with bedside flush toilets
Toilets	20–22 in. from floor
Bathing	Near nurses' station, must be supervised
Utility room	Near nurses' station
Pantry	Supervised, near nurses' station
Storage area, personal	Limited vertical storage; increase in horizontal storage
Nonpersonal storage.	Limited vertical storage; increase in horizontal storage
Treatment room	Near nurses' station
Family counseling	Near nurses' station
Nurses' station	Located for convenience of nurses

* Group I patients suffer severe physical handicaps but are emotionally and physically intact.

TABLE 2 Group II Facilities*

Area	Design requirements
Community room	Supervised
Physical therapy	Combined with community living
Exterior environment.	Supervised
Bedrooms	Sufficient area for wheelchairs, walkers, crutches; half of rooms with bedside flush toilets
Toilets	20–22 in. from floor
Bathing	Near nurses' station, must be supervised
Utility room	Near nurses' station
Pantry	Supervised, near nurses' station
Storage area, personal	Limited vertical storage; increase in horizontal storage
Nonpersonal storage.	Limited vertical storage; increase in horizontal storage
Treatment room	Near nurses' station
Family counseling	Near nurses' station
Nurses' station	Located for convenience of nurses

* Group II patients suffer severe physical and behavioral disability. Therefore they require total nursing care as well as major supervision of social activities.

Fig. 4 Group II, mentally and physically disabled.

Fig. 5 Group III, custodial.

Fig. 6 Group IV, mentally disabled.

Because, generally speaking, nursing home administrators cannot determine patient population beforehand—or they choose because of administrative and economic patterns to have a wide mix of patients, the common interpretation of the structure is to have the nursing and activity functions not flexible. This type of building is in a great degree determined by the relevant codes and the most economical means of construction. It has been our experience, however, that the criterion of initial low construction cost results in high administrative, maintenance, and operational costs, and as building costs are a very small percentage of what the patient pays, a debt service of \$2.50 to \$5.00 a day, it appears a false economy. Another factor that should be explored is that

operational care could be improved even in the uniform nursing unit if the design were determined to a greater extent by an awareness of the proposed patient population.

Regardless of what overview decisions are made, the design of the typical LTC is basically concerned with (1) the relationship of area size to the daily census in the facility, (2) the analysis of these areas in terms of the different functions, and (3) the criteria used in discerning the nursing unit layout and supportive facilities.

1. In most instances the program delineates the size of the LTC facilities. It is determined by such factors as available money for construction; the need within a community as determined by demographic factors or methods

TABLE 3 Group III Facilities*

Area	Design requirements
Community room	Unsupervised
Physical therapy	Not indicated
Exterior environment	Unsupervised
Bedrooms	Conventional
Toilets	Conventional
Bathing	May be located conveniently; nonsupervision permissible
Utility room	Not indicated
Pantry	Unsupervised, near community room
Storage area, personal	Increase in vertical storage; conventional horizontal storage space
Nonpersonal storage	Increase in vertical storage; conventional horizontal storage space
Treatment room	Not indicated
Family counseling	Near nurses' station
Nurses' station	Located for convenience of nurses

*Group III patients require little supervision because they present no, or very moderate, physical and emotional and social disability.

TABLE 4 Group IV Facilities*

Area	Design requirements
Community room	Supervised
Physical therapy	Not indicated
Exterior environment	Supervised
Bedrooms	Conventional
Toilets	Conventional
Bathing	Supervised, but located conveniently for patient
Utility room	Not indicated
Pantry	Supervised, near nurses' station
Storage area, personal	Increase in vertical storage; increase in horizontal storage space
Nonpersonal storage	Increase in vertical storage; increase in horizontal storage space
Treatment room	Not indicated
Family counseling	Near nurses' station
Nurses' station	Located to permit control of patient areas

*On the purely physical level, patients in Group IV need little nursing care but require maximum supervision because of emotional disability.

of health care, code requirements, site limitations; and, finally, the kind of operation as foreseen by the administrator or nursing home operator. The nursing unit is a prime factor in operational cost, and thus the size of the facility is usually a multiple of the number of nursing units. Because of the cost of operation of feeding, therapy, and administration, the larger the facility, usually the more economically efficient it will be, although too large a unit might not allow for adequate patient service functions. The average size in 1970 was 80 beds, and the present recommended criterion is that it should not be less than 120 beds. In high-operational-cost areas, economically viable nursing homes require a minimum of 200 beds. Once the number of beds has been determined,

the areas of the building can be calculated, bearing in mind such factors as the care given, the stipulation of single-bedded or multi-bedded rooms, and the community facilities provided. Again, in the typical facility at present, where community functions are non-existent or minimal and where the number of single- and multi-bedded rooms are determined by code or FHA regulations, etc., the size varies between a total building area of 250 and 400 sq ft per bed.

2. Although, as previously noted, it is desirable that the inter- and intraconfiguration be determined by the medical and social patterns of patient care, there are common facilities that are required for operation by codes and public agencies. Thus, in an overall sense, the design of all independent long-term care buildings will contain the following component parts:

1. Administrative facilities
2. Staff facilities
3. Public facilities
4. Medical, treatment, and morgue facilities
5. Dietary service
6. Storage areas
7. Work area and maintenance areas
8. Mechanical facilities such as boiler, air conditioner, pump
9. Patient, staff and visitor circulation patterns.
10. Nursing units including ancillary facilities—i.e., nurses' station, nursing unit dayroom
11. Supportive and rehabilitative facilities for patients, such as recreation, dining, therapy areas

The component parts listed above, except for items 10 and 11—the nursing unit and supportive facilities—are similar to those of general hospitals, and thus criteria developed for general medical facilities, as indicated in the section on "Hospitals," may be applied to the LTC facilities. Some indication of the ways in which the areas of the LTC differ from those of the general hospital are listed below.

1. Administrative Facilities Although there has been a great increase in staffing patterns in recent years nursing home administration facilities still require significantly less area and have fewer employees than do general medical facilities. The reasons for this are that nursing homes provide fewer medical, surgical, and laboratory services; administrative problems are reduced by the lower turnover of patients (less record keeping and billing); and, usually, there are fewer visitors per patient per day, although there may be more family counseling. The administrative employees in a nursing home would number between 5 and 10 per 200 patients, and the area required would be about 150 sq ft per employee. However, with the administrative and bookkeeping problems involved in government aid programs and other funding, there has been a remarkable increase in the required area for administrative purposes in recent years, and it is expected that this trend will continue. Generally speaking, there are the following areas: a business office; a lobby and information center; an administrator's office; an admitting and medical records area; an administrative staff toilet room, supervising nurses' areas; social service office; and staff conference room.

2. Staff Facilities As stated above, the reduced medical services provided, as well as the usual absence of staff physicians, results in a concomitant reduction of staff in an LTC facility as compared with a general hospital. Often the staffing is determined by patient population and is indicated in administrative codes, such as at least two registered nurses per facility,

one licensed practical nurse per 20 patients, and one aide per patients.³ These are usually female, whereas other employees, such as porters and kitchen workers, are mixed. Generally speaking, LTC facilities have $\frac{1}{2}$ to 1 employee per patient, and 80 percent of them are female.

The facilities needed are locker rooms, toilet and shower facilities, and dining room. There is some question as to the location of these facilities—whether they should be grouped in a separate area or distributed on each nursing floor with a smaller central grouping. There should be a central lounge, and it should be accessible to the employees' dining room.

3. Public Facilities The type and size of the public facilities depend to some extent on the type of sponsorship of the LTC facility; but one factor is constant: the number of visitors in the LTC facility is much smaller per patient than in an acute general hospital. This is often reflected in parking criteria and internal visiting areas. Where the general hospital may require one visitor parking space per bed, the LTC facility requires one visitor parking space for between 3 and 20 beds. Architectural features that are desirable are a visitors' lavatory on each nursing floor and, when the building is large enough, a small lobby with perhaps a snack and gift shop. When an LTC facility is community sponsored, a variety of public functions may be provided for it, but these would be similar to what is provided in a community supported general hospital.

4. Medical, Treatment, and Morgue Facilities As we have mentioned, both legislative requirements and medical practice require that major treatment of the acutely ill patient in the LTC be available within general medical and surgical hospitals. This gives the community an economical use of both staffing and facilities. Sometimes chronic hospitals in nonurban areas provide as part of their facilities intensive medical and surgical units; but with the notion of regional health care, this is not considered by most health planning agencies to be desirable today. The facilities in the LTC which are provided, where the law permits, are a diagnostic x-ray unit, a laboratory for hematology, biochemistry, etc., and, usually as part of the nursing unit, treatment rooms. It is desirable that spaces for dentistry, podiatry, and, on occasion, optometry, be provided if the patient population can support them. However, all these operations can usually be carried out in comparatively small areas.

The requirements for a morgue facility have varied with different localities and different regulations. It is ultimately a problem of operation whether they should be provided or not, but if required because of geographic or administrative reasons, the morgue is at best a small area used for storage of bodies for a few hours or a day or two at most. The autopsy procedure is a hospital function.

5. Dietary Facilities In the LTC as in the general hospital, the dietary requirements and the space and equipment required to support them are extensive and the basis for involved research and analysis.

Feeding is required for nourishment and as a patient activity, and, quite understandably, the social functions of dining are important

therapeutically. Feeding is accomplished in five different methods in medical facilities: (1) intravenous infusions, naso-gastric tube feeding, gastrostomy feeding; (2) with trays in bed; (3) at tables in patient rooms; (4) with trays in a controlled recreation room on the patient floor; and (5) family style in a controlled dayroom, in the nursing unit, or on a separate floor. It is understandable that methods 4 and 5 will be favored and used more frequently in the LTC. Here the social dynamics of group situations can be developed, and it is also a more efficient way of providing patient dining. Many have held that feeding intravenously or with trays in bed are undesirable in terms of an LTC facility, but they are occasionally used, depending on patient conditions. Feeding at tables in patient rooms is used more often because it is possible to control behavioral problems in this dining context. The size of the facility, however, is smaller, as the number of employees is much lower than in a general hospital.

6. Storage Facilities In the recent past considerable thought has been given to ways of resolving the storage problems of LTC facilities. Formerly large patient storage areas, as much as 25 sq ft per patient, were required, and there were minimal requirements for household supplies, linen, and furniture. However, the idea of the patient bringing possessions to the LTC to be stored is considered anachronistic, and the criterion used in designing storage areas today is about 5 sq ft per patient for personal storage and 5 sq ft for general hospital supplies and goods. The latter is less than what is allotted in a general hospital, because, as previously mentioned, the type of care required in a nursing home does not demand as many linens, pharmaceuticals, and supplies. However, the elements of hospital storage should be provided, and the importance of ensuring the flexibility of the compartments for this cannot be overemphasized.

7. Work Area and Maintenance Areas In general these are quite similar to those of the community hospitals, except that there is a minimum of medical equipment to maintain and that, although the number of patients may be similar to the general hospital, the total amount of equipment in the LTC requiring maintenance or repair is considerably less. We have found a single large room to be more than adequate in these areas for most LTC facilities.

8. Structural and Mechanical Factors During the last few years, the LTC facility has been designed to meet the structural and mechanical standards of the general hospital. As in most other medical facilities, problems, particularly of fire safety, have required fireproof buildings, often with sprinkler protection, smoke detectors, zoned floor areas, and rigid standards of fire resistance in terms of flooring, surfaces, and materials used. It is, of course, a fact that fire safety in a building housing many patients with behavioral problems (often involving carelessness and disorientation) is one of the major, if not the major factor in construction. While this appears evident, there are also other aspects of mechanical equipment criteria that are somewhat different than those for the short-term general hospital:

- a. **Lighting** It has been our experience that the level of illumination required for the LTC, bearing in mind the elderly patient population and their reduced sensory awareness and perception, is somewhat higher than that required in the patient

³ Another way of interpreting staff requirements is by using the New York State Code which requires of staffing time one hour of nursing care for ambulatory patients, two hours of nursing care for the semiambulatory, and four hours per day for the bedridden or wheelchair-confined patient.

NURSING HOMES

areas of the general hospital. Furthermore, the problems of safety require that all electric lamps and fixtures be firmly connected to a surface to avoid tipping.

- b. *Heating and Cooling* An imperative decision that has concerned the LTC administrator has been the method of heating and/or cooling. It is generally found that the elderly are far more likely to complain of being too cold than of being too warm. Therefore, in terms of the patient population, the provision of adequate heat without provisions for cooling has been considered satisfactory. Another factor is that the confused patient cannot be expected to reliably perceive or control his environment. Presently, the thinking is that the use of air-conditioning facilities is desirable, ideally with individual controls. However, even here there are problems for the patients in multi-bedded rooms.

- c. *Ventilation* A characteristic of many LTC facilities, because of the behaviorally difficult patient, is the problem of ventilation and the control of odors. It is a much more serious problem, at least for the staff and public, in this facility than in the general hospital and must be resolved by proper ventilation methods, the use of surface materials that do not retain odors, and the use of plumbing and furniture that allow for easy mopping and cleaning. The professional literature on this subject is extensive, and this aspect of mechanical equipment should be thoroughly researched before the LTC facility is designed.

9. Circulation Patterns The movement of people, goods and equipment in the LTC is for the most part similar in nature, if not in intensity, to that in general hospitals. The one special problem is the need of adequate control for the circulation of the behaviorally difficult patient, for often the need to control the movement of this type of patient comes into conflict with the need to provide free movement in terms of fire department regulations. The use of mechanical devices such as buzzers attached to fire doors, the shortening of corridors, the visual control of elevator doors, and controlled exits from the building are some of the factors that can help control the traffic problems involved with this patient population.

10. Nursing Units and Supportive Facilities An almost seminal practice in the design of LTC facilities is the placement of patients in autonomous nursing units, as it is believed that the control and management of patients can best be achieved in this manner. This nursing unit can be defined as a self-contained grouping of rooms, supportive facilities with unified control, all on one level. A basic decision is the size of the nursing unit, and while ideally the size of the unit will have a direct relationship to the degree and type of patient care provided in the unit, nursing home codes and governmental regulations generally set the number of patients cared for in a nursing unit between 30 and 60. In principle, the range could be even greater, as the spectrum of patients in LTC facilities is so varied. Thus as Table 3 shows, patients in Group III (custodial patients) could be in units of up to 100 beds, while patients in Group II (mentally and physically disabled patients) might be in units of 20 beds.

Concomitant with the decision as to the num-

ber of beds per nursing unit is the determination of the number of beds per room. Here the guidelines are medical operational criteria, hospital and administrative codes, and financial mechanisms. But also a very important consideration is the aesthetic and social values that the patient may have, and, even more important, those of the people placing him in the home. Thus, often patients with minimal cognitive awareness, requiring as much group support as possible, may be erroneously housed in single rooms because of social pressures.

Most thinking today is that the two-bedded room with adjoining or private bath should be the basic room pattern regardless of nursing unit size or type of care required, and that there should be a certain number of single rooms as well within the unit for medical and behavioral problems.

Codes require at least one single room per patient unit as an isolation suite with its own toilet, but often the requirements are that single rooms be available for 10-33 percent of the patients. However, the problem of the single or the multi-bedded room, as well as the other functions of the nursing unit, should (once the minimum code requirements are resolved) be determined by the criterion of what patient population would be served in the program given to the architect, and, as pointed out above, the criteria can range from minimum requirements to aesthetic and social values.

Supporting the idea of the autonomy of the nursing unit are the types of ancillary facilities that are part of it. The functions that must be provided are the control of the unit from the nurses' station, the preparation of medicines, the cleaning and providing of the entire range of supplies necessary for the patients, the supplying of supplementary food, and whatever bathing, recreation, dining, and training facilities are required. The question of whether patient treatment (e.g., surgical dressings, etc.) should be done in the room or in a separate treatment room depends on the choices that the nurses make. All of these functions are usually translated into representative areas as determined by the relevant codes. Listed in Tables 1 through 4 is an analysis of the types of areas, the required equipment, the minimum size, the function, and the relationships that seem to be generic in terms of regulations. The fact, of course, is that, depending on the projected patient population, the types and sizes of these facilities would vary. Thus, in Group III, medical preparation and treatment might be eliminated and the pantry might be made much larger than for other patient populations. However, most codes do allow, if not flexibility in the type of function required, a fairly wide range in terms of the size required.

The essential thrust in the design of the LTC is ultimately in the configuration of the nursing unit, and, as mentioned, the genesis of the choices available for this is in the operational program initially presented to the architect, or, even more salutary, when developed with the architect. In the overwhelming percentage of buildings, as has been stated, most of the plans are made for a variable patient population, ideally with a central nursing station adjacent to ancillary nursing functions that the nurse directly uses, with visual control of the patient corridors, recreation area, and means of entrance and egress. The size of the units, both for economy of structure and operation, is as large as the relevant code would allow. However, as has been pointed out, there is really little difference between this nursing unit

and a general hospital nursing unit, despite the fact that one is meant for an average 5-day stay and the other for an average 400-day stay. On a theoretical basis, Figs. 3 to 6 illustrate the correlation of possible unit configurations based on the patient population. While these designs would obviously be modified by code, medical practice, economy, and a difficult problem of determining the projected patient population, we believe they are valuable as abstractions indicating the correlation of care and planning.

11. Rehabilitative Facilities Rehabilitation and physical medicine is the primary medical discipline involved in LTC facilities. Present thinking is that, in terms of the aged patient population, rehabilitation should properly be both a physical and behavioral therapeutic process. For the most part, this therapy is not centered on making the patient operational in society but rather on providing adjustments for the patients to live with their disabilities. Just as difficult an aspect of this adjustment as the physically based problems are those problems generated by behavioral disabilities. While, broadly speaking, spaces for therapy have meant facilities for physiotherapy, hydrotherapy, and heat therapy, the fact is that facilities for social therapy or facilities for developing social groupings should be part of the overall planning.

The areas for physically based rehabilitation are required by code, but the type of medical care given in these spaces is usually determined by the medical staff and administration. Often, physiotherapy, both in exercise and manipulation, has been considered sufficient for the patient population, and the location of this space has been both in separate rooms and as part of the dayroom, as this would induce a greater incentive for the individual patient to perform in terms of a peer group. Whether this area is separate or part of other areas, the fact remains that the use of such apparatus as parallel bars, exercise wheels, etc., under proper supervision, is a vital part of the patients' care. The need for hydro and heat therapies in the LTC facility has often been questioned. Ultimately, the decision to use these latter therapies is either an administrative or governing regulation.

Recreational spaces are needed for the behaviorally based therapies or what is sometimes called occupational therapy, which can be considered both physical and behavioral therapy. Whereas a central area is desired, often the actual therapy takes place within the nursing unit dayroom.

Often considered the best behaviorally based therapy is participation in a social community, whereby, as it has been demonstrated, many of the anxieties and much of the loneliness that is a concomitant of the aging process can be reduced. These group situations may take the forms of religious services, lectures, group games, group teas; even a bar has been used. However, the most important aspect that generates one of the most difficult planning decisions is the development of a community within the LTC, whereby patients will be providing support for others. In terms of architectural configurations, spaces for this activity have been arranged so that sleeping rooms open directly onto living rooms, or they have been provided by eliminating halls and having spaces open into large community areas. It is through the exploration of this problem that architectural planning may be considered an aid of therapy as well. The size of these

TABLE 5 Typical Regulatory Requirements for LTC Facilities

Type and size of room	Activity	Nursing unit		
		Equipment and sizes	Relationship	Comments
Single (125 sq ft) Multi-bedded (100 sq ft per bed), cubicle curtains required	Depends on patient population. Will serve for both sleeping and general activity, and may also include dining, recreation, and therapy	Beds (usually gatch type) with side rails, 36 by 86 in.; overbed tables (usually not required); bedside cabinet, 18 by 20 in.; chairs, straight back and arms (at least one chair per bed) Storage Space: Vertical storage—robes, outdoor clothing in closets or wardrobes, 1 ft 8 in. wide by 1 ft 10 in. deep, should contain shoe rack and shelf Horizontal storage—cabinets or built-in drawers, 1 ft 6 in. deep (Note: Ideally, vertical storage areas should be increased for ambulatory patients and horizontal storage increased for nonambulatory patients.) Optional Equipment: Small table, ideally round with a heavy pedestal base; platform rocking chairs, where patient conditions permit; lavatory; cabinet for storing patient toiletries (Note: Where private toilet is used, lavatory may be placed in toilet.)	Not more than 120 ft from nurses' station	See plans; desirable distribution should be based on administrative practices
Toilet (3 by 6 ft) Toilet and lavatory (3 by 8 ft and/or 6 by 5 ft)		Required: Grab bars, toiletry cabinet and/or space for toiletries, mirror (Note: lavatory should be accessible to wheelchair patients.) Optional: Divert-a-valve, bedpan washer		
Nurses' station (minimum 6 lin ft of counter with access space on both sides)	Control of nursing unit charting communications, storage of supplies and nurses' personal effects	Patient charts (9 by 12 in.—May be movable or set into the desk), chart rack for 40 charts (4 ft wide by 16 in. deep), writing desk, legal files, cabinet storage area, outlets for nurses' call system, telephones		
Nurses' toilet room (5 ft by 4 ft 6 in.)		Toilet, lavatory, toiletry cabinet, mirror	Convenient to nurses' station	Although not desirable, often used as visitors' toilet as well
Clean workroom (minimum 8 by 6 ft)	Storage and assembly of clean supplies such as instruments, etc.	12-ft-minimum work counter with back splash, instrument sterilizer, 2 sinks, drawer and cabinet storage	No more than 120 ft from patients' rooms	
Medicine room, 1 ft 6 in. by 5 ft cabinet (mediprep unit)	Storage and preparation of medicine	Sink, refrigerator, locked storage (Note: Facilities for preparation of medication can in mediprep unit.)	Adjacent to nurses' station	May be a designated area within clean workroom if self-contained cabinet is provided
Soiled workroom (minimum 8 by 6 ft)	Cleaning of supplies and equipment	Clinical sink-bedpan flusher, work counter, waste and soiled linen receptacles	No more than 120 ft from patients' rooms	
Enclosed storage space (4 by 4 ft)	Clean linen storage			May be a designated area within the clean workroom
Nourishment station 5 lin ft of counter and work space in front	Supplemental food for patients during nondining hours	Storage area, stove, sink, refrigerator Optional: Icemaker, coffeemaker		May serve more than one nursing unit
Equipment storage room (4 by 6 ft)	Storage of intravenous stands, air mattresses, walkers, similar bulky equipment			
Patient baths (showers not less than 4 sq ft)		One shower stall or bathtub for each 15 beds not individually served, grab bars at bathing fixtures, recessed soapdishes		At least one bathtub in each nursing unit

TABLE 5 Typical Regulatory Requirements for LTC Facilities (Continued)

Nursing unit (cont'd)				
Type and size of room	Activity	Equipment and sizes	Relationship	Comments
Stretcher and wheelchair parking area (8 by 5 ft)		Open space	Easily accessible from hall, near exit and entrance of nursing unit	
Janitor's closet	Storage and cleaning of house equipment	Housekeeping supplies and equipment, floor receptor or service sink		Larger cleaning area desirable with garbage and linen chutes in vertical-type buildings
Nursing unit and patient activity areas				
Dayroom; total area for patient activities, 30 sq ft per patient. Minimum size, 300 sq ft	Controlled and multigroup activities, religious services, lectures, group games, group teas, dining (most frequently this is combined with the dayroom, but it can be separate). Recreational therapy often combined with this area	Upholstered sofas and armchairs, preferably with straight backs and designed for ability of patients to sit and get up; straight chairs similar to those in patient rooms; rocking chairs similar to those in patient rooms; tables with firm supports and round or rounded edges, accessible to and of a height for wheelchair patients (preferably with pedestal supports and round tops); television sets on low tables or ceiling-mounted lectern	Required floor day room ideally to be controlled by nurses' station; different medical programs generate different relationships	Generally nursing unit dayroom is 15 sq ft per patient; common day and dining room is 15 sq ft per patient
Physiotherapy minimum 300 sq ft, approximately 3 sq ft per patient)			Central to LTC circulation from nursing units	
a. Exercise space	Exercising, treatment and training in ambulation, stair-climbing, and activities of daily living	Parallel bars, exercise wheel, ambulation track shoulder ladder, convertible exercise steps		Structural reinforcement necessary for ceiling mounted ambulation track and wall-mounted exercise wheels
b. Examination and massage space	Manipulations and massaging	Treatment tables with pads (3 by 6 ft)		
Hydro and heat therapy area may be combined with physiotherapy. Size included in area above	Use of water movement and heat as massage	Mobile stands, hydrocollator (2 by 3 ft high), infrared lamp, whirlpools (partial- and full-immersion tanks), paraffin bath, patient lift, ultrasonic generator, microwave diathermy unit		Not usually required by code
Occupational or recreational therapy	Social and physical support in terms of creative actions	Hand looms, potter's wheel, painting equipment, easels, leatherworking tools, woodworking tools, sewing machines		Size of room varies depending on where activity is done. Often area is used primarily as a storage facility and for fixed equipment (i.e., kiln, etc.).

areas for social rooms is often delineated by relevant codes and average about 30 sq ft per patient, but usually the codes allow the distribution in either a nursing unit dayroom, floor lounges, or a common LTC dayroom to be done in terms of the administrative program. Again, the only rule we can recommend would be to arrive at this through the analysis of the particular patient population of the proposed facility. Listed in Table 5, in terms of the usual codes and regulations, are the typical patient activity areas, their size, the equipment they usually contain, and their relationships.

CONCLUSION

Mentioned above have been only the rough planning data of the design of LTC facilities. Microscopic analyses based on the kind of hardware patients with reduced manipulative

ability can use, the types of furniture (such as seating that would allow easy access without strain, beds that would be sufficiently protective, and tables that would be sufficiently sturdy), the kind of plumbing fixtures that the elderly patient needs, and the kinds of interior surfaces are part of the literature of professional magazines and should be examined in detail. The essential basis, though, for understanding these aspects of the LTC is the understanding of the patient.

Nor is it our intention to discuss the major problem of aesthetic values in terms of this patient population. The range of what aesthetic an LTC facility should generate, whether the criterion should be what society wants, what the employees want, what the children of the patient want, or what the patients want is a question that individual decisions must resolve, and these can, it is hoped, be based

on some empirical data. It is believed as well that the extended care LTC program should generate a building that emphasizes the quality of space required for a longer patient stay and that this quality should be different from that of the community hospital in both plan and form, visually and functionally. Finally, we should arrive at an architectural expression for this space that would be a rejection of institutional forms, such as long hallways, sterile color schemes, mechanistic furniture, purely utilitarian finishes, and an acceptance of the fact that sunlight, casualness, and comfort not only are desirable patterns but also are part of the therapy and well-being of the LTC patient.

The task of resolving this fundamental social problem of providing support for the ill aged is a social action that we have just begun to explore and to which architects can make a most meaningful contribution.

CHILD HEALTH STATION

CHILD HEALTH STATION

The diagram (Fig. 1) shows the desirable space organization for a child health station.

Preferred location for the carriage shelter is within the building if space permits. If the shelter must be outside, it should be placed in the lee of the building.

The various rooms shall have space for the following equipment:

Waiting Room

Desk and chair at control point between waiting room and entrance to weighing and undressing room, etc.; movable chairs, with ample space between and around them; demonstration table; play pen, within the waiting room, minimum area 60 sq ft; small chairs and table; bookshelves, 36 in high.

Public Toilet

Located off waiting room. Provide one normalized toilet, and one child's toilet, one lavatory, set 28 in from floor.

Weighing, Undressing, and Dressing Room

Table; Bench-type clothes hamper; 25 cubicles; slop sink.

Anteroom to Doctors' Offices

Chairs.

Doctors' Offices

In each office: desk; two chairs; large table; smaller table; lavatory (standard apartment type).

Utility Room

Table; refrigerator; four-burner gas range; combination sink and laundry tray (standard apartment type).

Nurse's Office

Located adjacent to the waiting room, it can be used also for isolation space. It will need a desk and a chair.

Staff Room

Table and chairs.

Staff Toilet

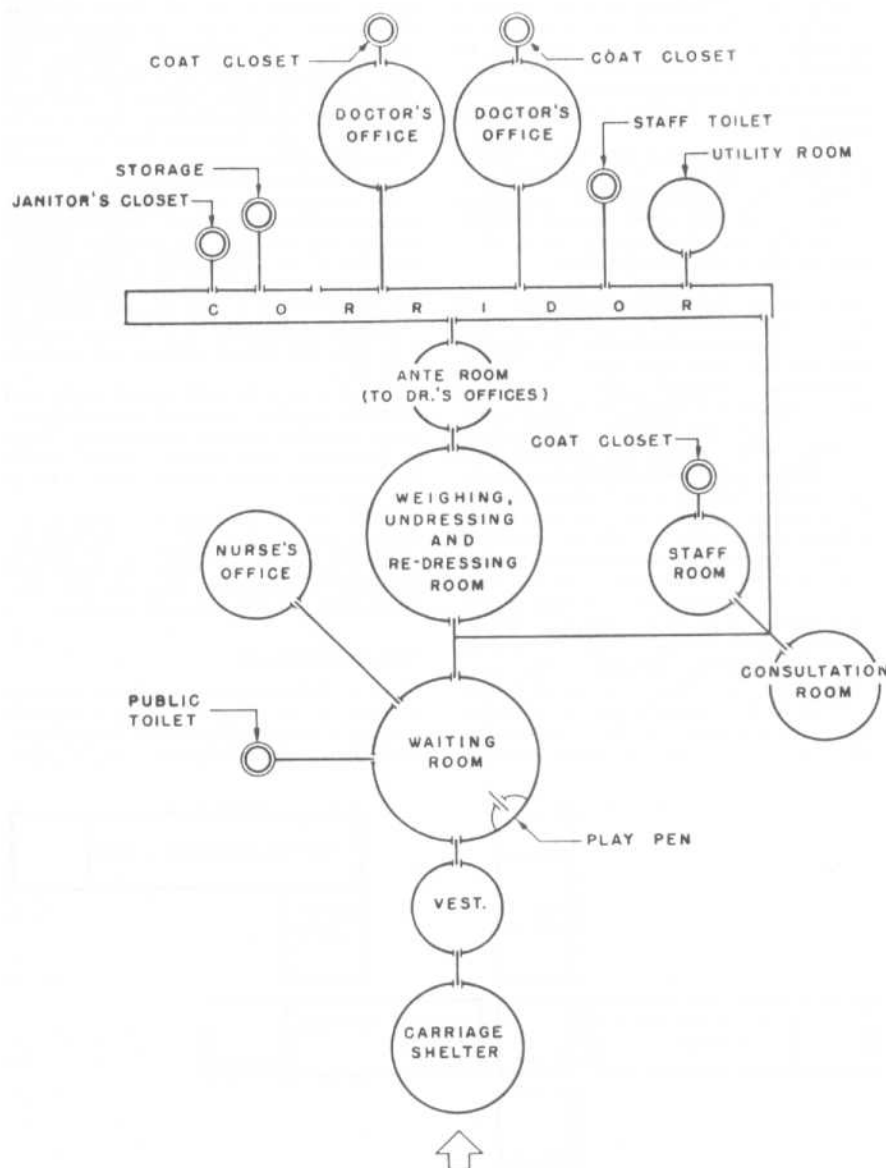

Lavatory and toilet.

Consultation Room

Desk, two chairs, table, and three file cabinets.

Slop Sink Closet

Must have space for cleaning equipment.

CHILD HEALTH STATION
SPACE ORGANIZATION

SITE AND PLANNING CONSIDERATIONS

Site

The modern medical center is so large and so complex that it should be located on the edge of the university campus rather than within it. This location will emphasize the fact that the medical center is a satellite in the university orbit, but has a degree of autonomy. It is important that students and staff in the medical center have easy access to the main university campus, and that the medical center be accessible to all areas of the university.

The site should be large enough to accommodate growth of the school programs and concurrent parking for at least 20 years. The minimum size recommended for a medical center including a teaching hospital is 50 acres, and 50 to 150 acres is preferable. Buildings should be placed on the site so that additions can be made as programs develop and as enrollment increases.

The service functions of the medical school involve patient care in hospitals and outpatient clinics. Growth of research and service responsibilities frequently leads to the development of specialized hospitals, such as children's, veterans', psychiatric, chronic disease, rehabilitation, or others. The site should permit location of these facilities in relation to the major teaching hospital so that staff and students can be within a five- to ten-minute walk. The teaching hospital and clinical science facilities should be placed on the site so that the educational functions relate to and connect with the basic science facilities. Outdoor facilities for rehabilitation of patients related to the clinic and recreation facilities for students related to housing should be provided. The extent of these facilities varies widely among schools. Adequate space for housing should be provided nearby. Apartment-type housing with play areas for children, within five minutes' walking distance of the hospital, is preferable.

Adequate parking facilities should be provided for students, staff, patients, and public convenient to each element of the medical center including housing. This may take the form of divided shopping-center-type parking, preferably with trees, various types of paved surface parking, or multilevel parking garages.

If possible, the site should be sloping so that more than one level of entrance to the buildings can be obtained and horizontal movement of supplies can take place at one level without conflicting with horizontal movement of people at another level.

The direction of prevailing wind should be studied so that buildings can be placed in relation to each other and to the campus and community to avoid windblown odors from cooking and incineration of animal waste and trash, bacteria from infected patients, chemical fumes, and low levels of radioactive isotopes.

The site for the animal farm is not usually contiguous to the medical center. However, a minimum site of about 25 acres should be

provided; recent studies indicate that 120 acres may be required. It should be located for convenient transportation to and from the animal quarters.

Functional Relationships

Of prime importance in planning medical schools is the relationship of its three major components: the basic science facilities, the clinical science facilities, and the teaching hospital. For the most efficient movement of students, faculty, patients, and supplies, the three should be interconnected, but for maximum flexibility in expansion each should be an independent element. Fig. 1 illustrates this relationship.

The basic science and the clinical teaching and research facilities, in turn, should be attached to the hospital to permit easy access to patient units and other hospital facilities. The diagram also shows the possibility of expansion inherent in this relationship.

In the basic science facilities, the departments can be stacked above each other with teaching laboratories, faculty, research and office space, and lecture rooms for each department located on the same floor. The cadaver preparation and storage department is usually located on a floor accessible to grade for convenience in handling cadavers. Central animal quarters serve teaching and research areas for both basic science and clinical departments. A location with direct connection to the circulation center and at grade level for access to a delivery entrance for animals is important.

Other common-use areas should be located where they are accessible to both the basic science and clinical departments. Thus, a basement location for such facilities as the radioisotope laboratory and technical shops is acceptable. Administrative facilities, school post office, snack bar, student lounge, and bookstore should be accessible from a circulation center and are generally placed on the first floor. Study cubicles for basic science students

should be convenient to both the medical library and teaching laboratories. The medical illustration area should be located for north light if possible.

Locating the clinical science facilities in connection with the circulation center provides access to the common-use facilities mentioned above. These clinical science facilities, similar to those provided in the basic science departments, consist of faculty research and office space, since third- and fourth-year students are taught in the hospital. Individual departments should be on the same floors as the patient-care units which they serve in the adjoining hospital. Study cubicles for third- and fourth-year students and house officers can be provided in the teaching hospital. Lecture rooms should be placed near the circulation center for greater flexibility of use.

The arrangements and relationships of the elements of the departments in both the basic and clinical sciences are generally similar. Facilities for an individual department should be on the same floor insofar as possible. Teaching laboratories and their auxiliary spaces in basic science departments should be separate from but near faculty offices and research laboratories.

Elements such as floor animal rooms and cold rooms, which are found in each department, should be stacked for economy. These facilities, together with lecture rooms, should be sized initially and located to take care of later expansion.

Toilet facilities should be designed to accommodate expansion. If located on a circulation center they will be accessible to adjacent departments. Separate elevators for passengers and supplies are recommended.

Program Assumptions

Because of the variations which exist among present schools and programs, it is apparent that space requirements for a new school cannot be stated dogmatically. There is great need,

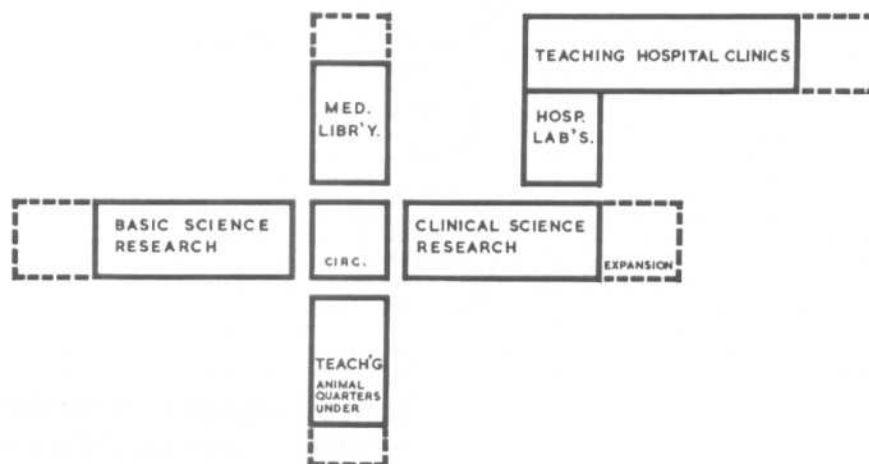

Fig. 1 Functional relationship of medical school elements.

however, for some benchmark for planning a new school.

In this section, it is assumed that the basic science facilities, clinical science facilities, and teaching hospital are contiguous.

The space considerations and requirements presented in this section are for two hypothetical schools including basic science facilities, clinical science facilities, and a teaching hospital. The first is School A, with an entering class of 64 students and a hospital of 500 beds; the second is School B, with an entering class of 96 students and a hospital of 700 beds.

School A

1. Is a four-year university-based school.
2. Provides space to house an entering class of 64 medical students, with a planned expansion to an entering class of 96 students. Enrollment in third- and fourth-year classes will be 60, with future expansion to 90.
3. Provides office and laboratory space for a full-time faculty of 35 in the basic science departments and 60 in the clinical departments.
4. Provides space for 40 graduate students and postdoctoral fellows in the basic science departments and 30 in the clinical departments.
5. Provides either conventional or multi-discipline teaching laboratories for the basic sciences.
6. Has its own library, with ultimate capacity of 100,000 volumes.
7. Has its own teaching hospital of 500 beds.
9. Has its own technical and maintenance shops, but heat is supplied from a central source.
10. Does not provide space for teaching students in other health professions such as dentistry or nursing.

School B

1. Is a four-year university-based school.
2. Provides space to house an entering class of 96 medical students with third- and fourth-year enrollment of 90 per class.
3. Provides office and laboratory space for a full-time faculty of 50 in the basic science departments and 85 in the clinical departments.
4. Provides space for 55 graduate students and postdoctoral fellows in the basic science departments and 40 in the clinical departments.
5. Provides either conventional or multi-discipline teaching laboratories for the basic sciences.
6. Has its own library with ultimate capacity of 100,000 volumes.
7. Has its own teaching hospital of 700 beds.
9. Has its own technical and maintenance shops, but heat is supplied from a central source.
10. Does not provide space for teaching students in other health professions such as dentistry or nursing.

GENERAL ADMINISTRATION AND SUPPORTING FACILITIES

General Administration

The dean of the medical school is responsible for the formulation and execution of policies of the teaching programs and for the general administration of the basic sciences, the clinical sciences, and the teaching hospital. Because of the magnitude and complexities of these programs, the dean will require assistance from competent persons in these fields. Table 1 gives the net area for administration.

TABLE 1 Net Area for General Administration

Type of facility	School A (entering class of 64 students)	School B (entering class of 96 students)
	Square feet	
Total	3,900	4,700
Dean's office	400	400
Assistant dean's office	200	(2) 400
Secretaries' offices	450	600
Conference room	500	500
Business offices	400	500
Registrar and alumni	250	300
Postgraduate office	250	300
Scholarship and grants	250	400
Records	200	300
Public information and publications	200	200
Public toilets	200	200
Waiting room	500	500
Storage	100	100

Medical School Library

The medical school library includes the offices, work areas, stacks, carrels, vaults, reading rooms, alcoves, conference rooms, audiovisual rooms, and other related spaces required by the maintenance and service responsibilities connected with the care and use of recorded medical information.

In programing and designing the medical school library, consideration should be given to the probable impact of future regional branches of the National Library of Medicine and the computer-based bibliographic retrieval and publication system called MEDLARS—Medical Literature Analysis and Retrieval System.

The medical school library should be located so that its resources are quickly available to students, research workers, faculty members, hospital staff, and practicing physicians. Unless there are large medical research collections nearby, the library should be equipped to accommodate 100,000 volumes and 1,600 scientific periodicals.

Table 2 gives the net area for a medical school library of 100,000 volumes and 1,600 periodicals. Since medical library collections tend to increase rapidly, the library should be planned for future expansion.

In designing the library, maximum flexibility should be a prime consideration with necessary divisions in the form of partitions which can be moved.

Shelving, whether in stacks or in reading areas, should be standard library equipment, with standard interchangeable parts. Standard sections, usually 3 ft long, should be used throughout, with only such exceptions as floor layout may demand. Those for medical books have a shelf depth of 10 in. One 3-ft-long single-faced section will accommodate approximately 100 volumes.

Service aisles between stacks should not be less than 3 ft wide. Main aisles should be at least 3 ft 6 in. wide. If bookstacks are on more than one level, or are not on the level where books are received, vertical transportation must be provided.

Students and faculty members should have free access to stack areas, which should be provided with carrels for work and study.

These are usually alcoves, preferably adjacent to windows, each equipped with a desk, reading light, and chair. They should be provided at the rate of one for each ten students. However, fewer may be required if individual study cubicles for students are provided elsewhere.

Other rooms often associated with the stack area are a microfilm storage and viewing room and a room for the storage of motion-picture films and slides. A relatively soundproof room for photoduplication facilities is necessary. An area for general reading and open-shelf reference work may be supplemented by a number of smaller reading areas, rooms, or alcoves. The main reading area should be near the main catalog and circulation desk. If individual student study cubicles are not provided in the school, student reading areas in the library should accommodate from 25 to 50 percent of the total enrollment of the medical school and students from other programs who require access to the collection. Students seated at tables require a minimum of 25 sq ft of space each. Additional seating allowance should be made for faculty and research staff and other users.

A separate alcove with shelves, or a section of shelving in the main reading area, should be

TABLE 2 Net area (in Square Feet) of Facilities Required for a Medical School Library of 100,000 Volumes and 1,600 Periodicals

Type of facility	Schools A and B (entering classes of 64 and 96 students)
Square feet	
Total net area	29,560
Public services:	
Total	24,950

Historical librarian's office	120
Office storage	80
Staff room	400
Staff toilets and lockers	240
Housekeeping	240

MEDICAL SCHOOLS

provided for unbound journals. If sloping display shelves are used for current issues of journals, open shelving underneath for housing unbound earlier issues are more convenient than closed compartments.

A room with paging facilities may be provided for the use of those on call. Small study rooms for group conferences of four to six persons each should also be included. An area should be provided in the lobby or near the reference desk containing nontechnical books for browsing. A film- and slide-projection room and a sound-tape room, each to accommodate 16 students and an instructor, may be required depending on the program. Both rooms should be soundproofed and designed so as not to distract readers in other areas. A microfilm reading room is necessary. A medical history room may be required and may be a combined medical history and rare medical book room, in which case protected windows, doors with locks, a fireproof vault, and special air conditioning will be required. Well-lighted exhibit cases should be provided adjacent to the entrance to the library and its main lanes of traffic. Public toilets, rest rooms, coat rooms, and janitor services should be convenient to the reading areas.

The book charging desk, located near the entrance, should control the exits from reading areas, workrooms, and stacks to minimize book loss. The card catalog should be close to the main entrance and near the circulation desk and the acquisition and cataloging rooms. In the staff workroom a sink should be provided. Provisions should be made so that noise generated by activities at these areas does not distract readers.

One workroom subdivided into alcoves by double-faced bookshelves may be provided, instead of separate workrooms, for acquisition and cataloging. These rooms should be near the public catalog and should have direct access to the stackroom; 100 sq ft should be allowed for each staff member.

The reception-secretary's office should be adjacent to the head librarian's office. A departmental conference room may be required. The head librarian's office should be accessible both to the staff workrooms and library clientele.

The receiving room is best located on the ground floor with access to an unloading platform. A work table, shelving, and shipping equipment should be provided. Lift service, preferably an elevator which will hold loaded book carts, between the receiving room and the acquisitions department should be provided where these areas are on different floors. Vending machines for food and drink should be located outside the library proper and be provided with space for tables.

Animal Quarters

The need for controlled care of animals to meet teaching and research requirements is reflected in the provision of a central animal service in an increasing number of medical schools.

The location of animal quarters on the ground floor, where direct-connected outdoor animal runs and truck unloading facilities can be provided with complete separation from any other function, has many advantages. A separate entrance to serve the animal quarters is essential. Provision should be made for expansion in the initial planning.

However, a vivarium in an adjacent wing with its own vertical transportation for animals, animal supplies, and personnel may serve the

needs of research better than an animal facility at grade level. The floors of the vivarium should communicate with those of the adjoining structure so that animal rooms are horizontally contiguous to the research and teaching laboratories using them and so that animals can be transferred to the laboratories without traversing corridors of other areas. If a vivarium is provided, animal-holding rooms are not usually required within research areas.

Animal quarters are composed of a number of different kinds of areas. Each has its own requirements in terms of space and location. In animal areas, provision must be made for the reception, quarantine, and isolation of incoming animals near the animal entrance; for housing different species; for exercising animals; and for specific research projects. Isolation rooms for infected animals, each with a vestibule containing facilities for gowning and scrubbing, are required.

Table 3 gives the net area for animal quarters.

Animal rooms should be isolated from each other with no connecting openings and arranged to separate clean and contaminated functions. A service corridor may be provided in addition to the main access corridor to allow the removal of soiled bedding and other material at the rear of a range of cages rather than through the main corridor. Borrowed light in corridor partitions and between rooms should be avoided since light bothers some animals. Windows, if used, should be placed at least 6 ft above the floor so that animal cages can fit below them. Each room should have a sink

and soap dispenser. A vestibule at the entrance to a block of rooms where the attendant can change clothes and shoes is recommended to help reduce infection.

The construction of animal quarters should be fire resistant, vermin- and insect-proof, and above all easy to clean. Recesses, cracks, and pockets should be avoided. Bases should be coved. Special attention should be given to such openings between rooms as pipes, conduit, and telephone wiring. Doorsills will prevent water from leaking into the corridor when floors are washed down, but are not as convenient for moving cage racks in and out of rooms.

Wall surfaces should be smooth, hard, and easily cleaned. Ceramic tile is often used but is easily damaged by cage racks. For protection of wall surfaces from such damage, a 6-in. curb may be provided. Cinder- or concrete-block walls must be laid up with tight joints and covered with a moisture-resistant material.

Doors should be 3 ft 6 in. wide to permit easy passage of cage racks, and all hardware should be recessed.

Floors must be able to resist the disintegrative action of the organic salts and acids in animal urine. Quarry tile with acid-resistant joints is satisfactory but should not be used in the corridor because of the noise created by cage carts as they bump along the joints. Concrete floors, well compacted and troweled, are also satisfactory. Asphalt, rubber, and vinyl tile floors are not recommended.

Floor drains are suggested for monkey and dog rooms. These should be 6 in. in diameter of the flushing type with special hair traps to avoid clogging. Use of floor drains in smaller animal rooms will depend on whether the rooms are hosed down regularly or swept and wet-mopped.

Departmental Offices

Each basic science and clinical science department faculty member requires office space for his departmental activities and laboratories for research. The head of each department requires an office with a desk, reference table, and space for a conference of several persons located near his research laboratory and adjacent to a secretary's office (see Fig. 2).

The conference room, which will be used for meetings of groups of students, should accommodate about 20 persons. Shelving for departmental books and periodicals and storage space for slide projectors, models, and other visual-aid equipment, chalk boards, and roll-up projection screens should be provided. In the clinical departments, x-ray view boxes are required.

The secretary's office may handle the secretarial work for the entire department and should be sized for the ultimate expansion of the department.

For space estimating, a unit of sixteen modules may be used as the primary unit for each department. The balance of the staff can be housed in additional eight-module units each accommodating five or six people and providing laboratory, office space, and supporting facilities. An additional two-module space is required for each additional faculty member.

Research Facilities

Research laboratories should be provided for faculty members, postdoctoral fellows, and graduate students in each department.

TABLE 3 Net Area for Animal Quarters

Type of facility	School A (entering class of 64 students)	School B (entering class of 96 students)

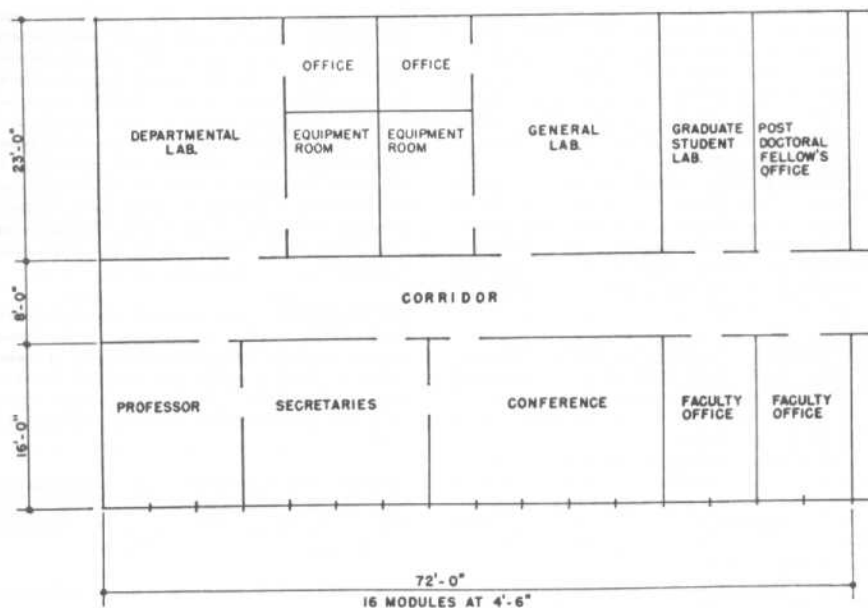

Fig. 2 Diagram for departmental office and research area.

The use of modules in planning laboratory facilities permits flexibility in utilization of space where changes in space requirements are common. Utilities and duct connections should be so provided that when space is changed utilities are available without undue pipe runs or perforations of walls or ceilings.

The equipment of research laboratories will vary with the kind of activity performed in them. It should be possible to rearrange work counters, microscope benches, and sinks, and to vary the size of the room as required without undue labor, inconvenience, or expense. This is most easily accomplished if all utilities and ducts are properly sized and located so as to make them available to all parts of the laboratory wing. This includes space not designed originally for laboratory use.

Some possible arrangements of research laboratories are shown on Fig. 3. The fume hood is shown on the corridor wall for convenient relation to the duct space.

Counter heights will vary—31 in. for sit-down work and 37 in. for stand-up work are most commonly used. The choice of a peninsula or island counter in larger laboratories may vary with the research project. Island counters can be used on all sides but are more expensive to install and alter; peninsula counters are more flexible with respect to air, vacuum, water, gas, drainage, and electrical services required.

An additional two-module space adjacent to the large laboratory can be divided to provide an office for an instructor and a special instrument or storage room. A two-module space may be used for four study cubicles for post-doctoral fellows.

Cold rooms are required in the laboratory wing of each department. They are refrigerated rooms for several workers who do procedures at low temperatures. A counter with sink, undercounter cabinets, and shelving are usual equipment. Electrical, air, and vacuum connections are required. All safety features such as safety door latches and warning lights should be installed.

The term "animal-holding room" is used to designate areas within a basic science or clinical department where small animals are held for a short time. These holding rooms, located close to an elevator which also serves the central animal quarters, eliminate the hauling of animal cages through public corridors. The animals are assigned to a staff member conducting studies requiring close, periodic observation or experimentation over a short time for a limited number of animals. These rooms may also be available to medical students performing animal experiments. Space is required for racks of cages, often placed back to back in the center of the room, with a single line of racks placed against the walls.

Animal operating and recovery rooms should be located in central animal quarters. Where vivaria are provided on each floor adjacent to departments, they should substitute for animal-holding rooms.

If properly located and provided with the necessary utilities, storage rooms can be used for expanded research activities. Those shown on the accompanying space diagrams are located and sized to allow for expansion. A four-module central equipment room should be provided in each department.

Auditorium and Lecture Rooms

The auditorium and lecture rooms are important teaching facilities for all the medical

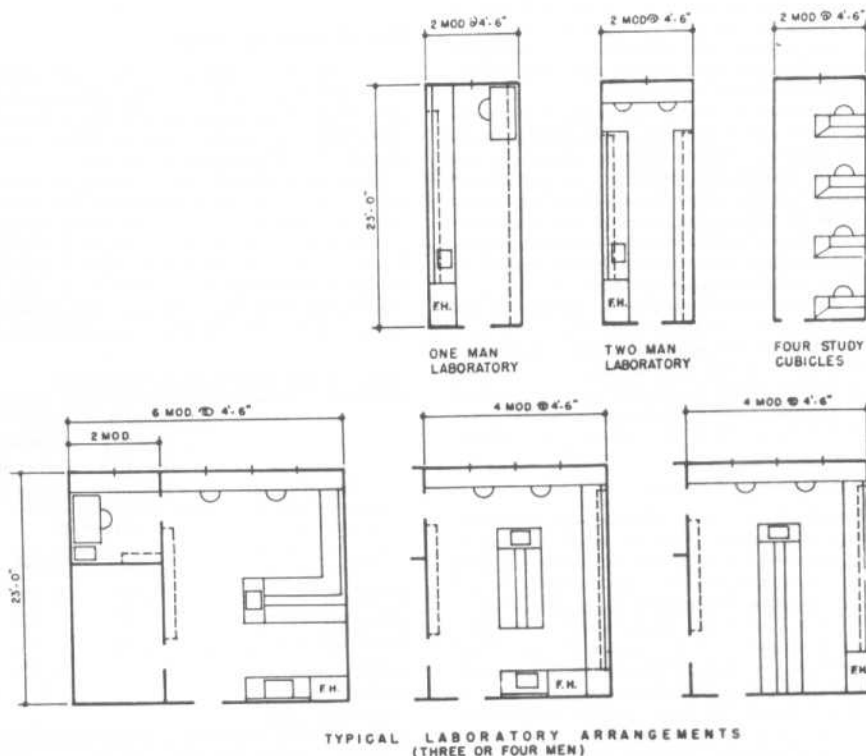

Fig. 3 Layouts for research laboratories.

MEDICAL SCHOOLS

school departments and the teaching hospital. They should be located for convenient use by faculty and students from the clinical departments, the teaching hospital, the basic science facilities, and by outside groups.

Auditorium The hospital auditorium is necessary to any medical education program. It is used for demonstrating patients to students and should be attached to the teaching hospital so as to provide maximum convenience and the least movement of patients. Ramps should be provided for bringing in wheelchair and stretcher patients.

The minimum seating capacity required for teaching in a university hospital auditorium is equal to the total number of students in the third- and fourth-year classes plus 50 percent additional seats.

A second auditorium or additional lecture rooms may be required since prolonged use of the lecture facilities may conflict with regular undergraduate teaching schedules.

For auditoriums, most authorities prefer fixed seats with dropleaf tablet arms, arranged in theater fashion with a sloping floor. The auditorium should have a low stage to facilitate the demonstration of patients and should be equipped for the installation of closed-circuit television. Projection facilities for sound films and slides, lighting controls, chalkboards, public-address systems, and closed-circuit television for doctors' paging should be provided.

Lecture Rooms A significant portion of the instruction in a medical school involves the use of lecture rooms.

A minimum of three lecture rooms should be provided in the *basic science facilities* as follows: two sloping or stepped-floor lecture rooms of 120-150 seats each for use primarily in basic science courses, and one sloping or stepped-floor lecture room of 80 seats for graduate-student instruction, continuation education, and other programs. Table 15 gives the area for lecture rooms for a hypothetical basic science facility.

Two 150-seat lecture rooms of sloping or step-floor type should be provided as part of the *clinical department facilities and the teaching hospital*.

Lecture rooms included in the tables are sized to accommodate a class of 96 students, with 25 percent additional seats. Although a class size of less than 96 students may be contemplated in the initial planning of a new medical school, it will be advantageous to construct lecture rooms on the basis of the maximum class size.

The main entrances to lecture rooms should be located at the rear, although corridor access to the demonstration areas of lecture rooms is essential for bringing in tables and other large equipment.

A minimum distance of 10 to 12 ft should be provided between the first row of seats and the back wall of the demonstration space.

Fixed seats with dropleaf tablet arms are generally preferred for lecture rooms. Such seats are usually 26 in. in width and require a minimum back-to-back spacing of 36 in. For a rough estimate of lecture-room seating-area size, including aisles and crossovers, 10 sq ft per person may be used.

Demonstration areas in all lecture rooms should be equipped with chalkboard, x-ray film illuminators, and roll-up projection screens. A lavatory may be necessary for the demonstration areas.

A projection area with platform, projector table, and convenient electrical outlets should be provided in each lecture room. Sound amplification equipment with conduits for loudspeakers for sound movies should be installed. Projectors are noisy and some sound-absorbent baffling may be required if a separate booth is not provided.

Auxiliary spaces which may be required for the use of the lecture rooms, such as storage rooms for visual aids and portable equipment, coat-rooms, toilet rooms, and telephone booths, will be determined by the individual school. Public toilets should be convenient to lecture rooms.

Study Cubicles Consideration should be given to the use of study cubicles within the basic science and clinical departments for post-doctoral fellows, and in the teaching hospital for the house staff.

Cubicles for medical students in the first two years should be located in the basic science area. For third- and fourth-year students, cubicles should be in the teaching hospital. Table 15 gives the net area for cubicles for hypothetical schools.

Each cubicle contains a desk with drawers on one side; a cabinet above the desk for books with a built-in fluorescent study light underneath; and a locker which, in addition to hanging clothes, may be used for microscope storage. A duplex outlet is necessary to attach the microscope. The locker not only provides privacy by forming a barrier, but also eliminates the necessity for separate locker rooms.

An allowance of 50 sq ft per cubicle is adequate. This includes desk, locker, chair space, and adjacent aisle. If aisles are double loaded (cubicles on either side), privacy for the student may be obtained by staggering the cubicles so that desks are not directly opposite each other.

It is desirable to have a lounge area nearby where discussions among small groups can be held without disturbing students in the study cubicle. Chalkboards and tackboard should be provided in this area and vending machines should be available.

If the study cubicle-clothes locker combination is not used, separate *student locker rooms* for male and female students should be provided. To conserve students' time and to ease elevator traffic, locker rooms should be located close to the line of travel to teaching areas. The proximity of the hospital should determine the necessity for separate locker rooms for third- and fourth-year students.

A *toilet room* should be connected to each locker room or study cubicle area and showers should be provided in the basic science area. If study cubicles with lockers are installed, a dressing room is required adjacent to toilet and shower room in the basic science facilities. A rest room for women should be included.

Student Activity Facilities

Lounge Space may be provided for such activities as pingpong, billiards, and card playing. A recessed or screened area with vending machines is desirable. A kitchenette for preparing coffee and snacks is provided in some schools. Shelving for books and current magazines, an aerial for TV, and a storage closet adequate for card tables, phonograph records, and other equipment should be provided. Public and house telephones should be available.

Table 4 gives net area for various student activity facilities. Facilities should also be provided for outdoor recreation.

Activities Office A student activities office near the student lounge may serve as headquarters for such activities as student organizations, honor medical societies, student publications, and student council, and may be the center of inquiry regarding athletic, recreational, and social events. There should be space for typewriter desks, file cabinets, and shelving. If the activities office is to serve as an information center, a service counter and bulletin board would be desirable. If the office is to be used for student publications, space for duplicating machines will be required.

Laundry Collection The medical student often wears more than one coat per day in the basic science courses. To maintain a supply of clean linen, a laundry collection station convenient to the student lounge or locker room should be provided with a pickup and delivery counter.

Bookstore The bookstore, although primarily for students, should be available to all persons using the building. Its location on a main floor of the medical school is preferable.

Health Office A student health office will serve the entire four-year student body, half of which will be studying in the basic science areas, the other half in the hospital. Locating the health office adjacent to medical school administrative offices may be desirable if they are near the hospital. Otherwise, a hospital location is suggested.

The health office should have a waiting area, an office area, and an examining room and should provide space for a medical cabinet, a small domestic refrigerator for storing pharmaceuticals, an examining table, a portable examining light, weighing scales, storage cabinet for incidentals, a clothes rack, and a lavatory.

Medical Illustration Service

The demand in medical schools for visual material to implement teaching, research, and patient-care programs is so great that a centralized medical illustration service for the production of such material is required.

Space required will depend on the extent of activities and number of personnel. The activities of a medical illustration service are divided into graphic arts, plastic arts, and photography. Closed-circuit television as a teaching aid is usually a separate service but may be a part of the medical illustration service. The medical illustration service usually is responsible for

TABLE 4 Net Area for Student Activities

Type of facility	School A (entering class of 64 students)	School B (entering class of 96 students)
	Square feet	
Total	1,850	2,400
Lounge and toilets	1,000	1,200
Student activities office	200	200
Laundry collection	200	400
Bookstore	450	600
Health office and examination area*		

* May be in hospital or part of general university health service.

maintaining the slide and movie projectors used throughout the school and facilities for repair and storage of such equipment should be provided. (See Table 5.)

Activities to be considered in planning the graphic art section include drawing, painting, and airbrush work, drafting for charts and technical diagrams, mechanical lettering, and general art work required in preparing displays or scientific exhibits. A large, well-lighted room, subdivided into work areas, is usually satisfactory. If possible, the area should be provided with natural north light.

The activities of the plastic art section include the skilled operations required to produce three-dimensional models of the organs of the body. These activities require a room for working with the patient in addition to the main work studio. Since the activities involve close color matching, both the studio and patient room should have north light.

TABLE 5 Net Area for Medical Illustration

Type of facility	School A (entering class of 64 students)	School B (entering class of 96 students)
	Square feet	
Total net area	2,020	3,170

Light lock	50	50
Darkrooms (2)	140 (2)	140
Loading room	30	30
Mixing room	60	60
Laboratory	190	190
Finishing room	70	70
Audiovisual: TV studio (in- cluding control area)		800

Activities to be considered in planning the photographic section of the department are photographing patients, both still and cine, photomicrography, copying, film processing and printing, film and print drying, film loading, chemical mixing, print and slide finishing.

Photographing human and animal specimens is a regular activity of a photographic section, but, because of the hazards involved in handling fresh specimens, this work should be done in or near the autopsy rooms.

A studio for photographing patients is required; two are preferable—a main studio for full-length studies and a "closeup" studio for photographing the head, extremities, eyes, and mouth. The wall of the main studio serving as a background should have a plain, smooth surface for at least 12 ft of its width. The adjacent floor space or patient area should be the

same tone as the wall with a 3-in.-radius cove at the base of the wall to prevent a strong line of demarcation between the floor and wall in full-length studies. A height scale on the wall at one side of the background area is desirable. Electric outlets should be provided at either side of the patient area for floodlamps and other portable lighting equipment. An adjacent patients' dressing cubicle and a lavatory with wrist-action valves are necessary. The door for admitting patients to the studio should be at least 44 in. wide.

For making 16-mm. motion pictures, about 35 ft between background and camera is required to prevent distortion. However, it is possible to back the camera into an adjacent work area to attain this distance. Sometimes a draw curtain is provided between the main studio and the "closeup" studio to facilitate this arrangement.

A separate room for photomicrography permits the photographer to work in the dark, which is frequently necessary; permits him to leave the equipment set up; and minimizes dust. The room should be near a darkroom.

Copying charts and drawings is frequently done in the main studio. Copying radiographs, however, requires a small room that can be darkened. Both types of copy work can be done in this room.

The smallest photographic section will require two darkrooms, one for films and one for contact prints, enlargements, and lantern slides. If color films are to be processed, a special darkroom for this purpose should be provided. The volume of color printing will indicate whether a special darkroom for this purpose is warranted. Darkrooms should have a sink along one wall and a bench along the other, with 3 ft of work space between them for one occupant or 4 ft for 2. Film and print driers may be located in any open work area near the darkrooms.

A room for loading film holders reduces traffic. A small, well-ventilated room, with a sink for chemical mixing, is necessary to protect equipment and materials against chemical fumes.

It is desirable to provide a small room for motion-picture film editing and titling, and for binding slides. Other finishing operations such as spotting, trimming, and mounting may also be done in this room. If projection equipment is included, motion pictures and slides may be checked.

A storage room for supplies should be provided. At least one refrigerator should be included for storing color material.

A storage room should also be provided in the general storage area of the building for the service. Some of the material handled may be a fire hazard and protective provisions should be made.

Technical Shops

Central technical shops are required as a supportive facility to all departments of a medical school. However, specialized shops may be required in some departments. The use of shops elsewhere on the university campus is not usually satisfactory from the standpoint of time or accuracy.

Technical shops usually include separate areas for metalwork, woodwork, glassblowing, and electronics. A metalworking shop usually requires a metal lathe, a drill press, two milling machines (one horizontal and one vertical), a metal-cutting band saw, a bench grinder, and a universal tool and cutter grinder. Storage

racks for bar and plate stock, tool cabinets and racks, and a machinist's bench will also be required. The woodworking shop needs space for a table saw, a thickness planer, a jointer, a wood lathe, and a drill press. A heavy wood bench, lumber racks, and tool cabinets should also be included. The glassblowing and electronics shops may be similar to those described for the department of biochemistry but on a larger scale.

Each technical shop should have space for a desk and files to record stock purchases and maintain requisitions from individual departments. The area for technical shops is given in Table 15.

Service Facilities

Table 6 gives the area for service facilities.

Telephone Facilities The teaching hospital will need switchboards. If the medical school is close by, a central telephone system may be advantageous. Combining the switchboard and information center is not recommended for a medical school complex. The switchboard is therefore best located in an area inaccessible to the public. A doctors' call system will be required in the hospital.

Postal Facilities A postal facility in the medical school may assume the normal duties of a post office and handle the distribution of interoffice correspondence. If the teaching hospital is adjacent, a central facility of this type will reduce duplication of mail handling and delivery.

TABLE 6 Net Area for Service Facilities

Type of facility	School A (entering class of 64 students)	School B (entering class of 96 students)

¹ 2 offices and secretaries.

² Central storage spaces for each department are listed on the department tables. However, areas for this storage are grouped here.

MEDICAL SCHOOLS

Central Storage Storage spaces within the department are discussed under other headings, but, in addition, separate storage space should be provided for each department elsewhere in the building. The amount of space for departments should be determined by their needs and designed for expansion.

A general storage room near maintenance shops should be provided for fixtures and equipment required for building maintenance and operation.

Each department should have a partitioned space for bulk storage. Because of variable loads of stored items, it is preferable to locate storage areas on a basement floor to avoid special floor live loads.

Central areas for storage and dispensing of bulk supplies of gases such as acetylene, argon, and hydrogen, and flammable liquids such as alcohol, acetone, and xylene, require specially designed space readily accessible to loading platforms and receiving areas. These areas must comply with applicable codes.

Locker and Toilet Facilities Locker and toilet facilities should be provided for male and female service personnel convenient to the employee entrance.

Snack Bar Vending machines for food and drink serve as a convenient type of snack bar.

Another type includes facilities for short-order foods, a service counter with stools, a table seating area, and a preparation-storage room. Allocation of space for a cashier counter and vending machines may be desirable. The snack bar should be convenient to the center of activity.

Maintenance Shops Maintenance shops required by the medical school and hospital usually include a mechanical and plumbing shop, an electrical shop, a carpentry shop, and a paint shop. Where the medical school and hospital are under one roof or in close proximity, a single set of maintenance shops may serve both.

The plant engineer usually has the responsibility for coordinating maintenance and repair activities. He requires an office with space for a desk and correspondence files, a secretary's office suitable for one secretary, files, and waiting space, and usually needs a separate drafting room with tables and plan-filing facilities.

Duplicating Room A central duplicating facility may be required if each department does not have duplicating facilities within the department. Some schools have set up a print shop in addition.

BASIC SCIENCE FACILITIES

Ideally, basic science, clinical science, and teaching hospital facilities are contiguous because of the close interrelationship of their functions in the teaching of clinical medicine.

Conventional and Multidiscipline Laboratories

Basic science departments have certain common elements, the most outstanding of which are the teaching laboratories. Two types of laboratories are in use in medical schools today: conventional laboratories, where each department has its own laboratories or shares laboratories with another department requiring similar facilities and students move from one laboratory to another; and multidiscipline laboratories where students are assigned

work spaces and all disciplines except gross anatomy are taught in this laboratory.

With the exception of gross anatomy, the basic sciences may be taught in either conventional or multidiscipline laboratories.

Conventional Laboratories If conventional laboratories are used, the following considerations must be taken into account:

- Laboratories are usually sized to accommodate an entire entering class. They are sometimes arranged for division, by means of folding partitions, into groups usually of 16 students (Figs. 4 and 5). One laboratory is usually assigned to each of the disciplines in the basic sciences, although in some instances several departments—for example, physiology and pharmacology, and pathology and microbiology—may use the same laboratory.

- Laboratories are generally referred to as sit-down or stand-up laboratories. Sit-down laboratories are provided for microbiology, microanatomy and neuroanatomy, and pathology. In physiology, pharmacology, and biochemistry, most of the work is done standing up. In sit-down laboratories, however, some stand-up work is done, and it is customary to provide stand-up counters for special instruments and reagents which may be shared by groups of students.

- Auxiliary rooms are required. These include preparation and issuing rooms, glassware processing rooms, storage rooms, and media-preparation rooms. Some schools place large and noisy pieces of equipment shared by groups of students in a separate instrument room.

- Graduate students usually use the same laboratories as medical students for classroom laboratory work. If separate facilities are provided, they are located close to the

auxiliary rooms. The design is similar but size will vary with the teaching program.

Multidiscipline Laboratories The multidiscipline laboratory is sized to take the number of students assigned to one teacher, usually 16 students, although some schools assign 24.

Except for dissection, the student will do all his laboratory work in this room; therefore, both sit-down counters, 31 in. high, and stand-up counters, 37 in. high, are required. In addition, movable tables 37 in. high are required for animal work for physiology (Figs. 6 and 7).

Table 7 gives the area for multidiscipline laboratories.

Each student is assigned a space containing about 4 ft of stand-up counter and the same length of sit-down counter opposite.

Utilities, storage, sinks, and general design and finishes of both stand-up and sit-down space will be similar to that for conventional laboratories. Chalkboards should be visible from each student space. Bulletin boards should be located near the entrance.

An equipment room is provided adjacent to or between each pair of multidiscipline laboratories in some designs. Equipped with a fume hood, counter space with utilities and cabinet space, it houses equipment required for the work in adjoining laboratories. Equipment such as centrifuge, freezers, and refrigerators are available to more than one laboratory.

The laboratory manager's office, secretary's office, and office space for one or two assistants should be provided. In addition, a ready storage room, a student issuing and supply room, a chemical storage room, cold room, and glass-washing room are required. If media preparation or slide preparation are to be done here, space for these should be provided.

TABLE 7 Net Area for Hypothetical Multidiscipline Laboratories

Type of facility	Square feet	
	School A (entering class of 64 students)	School B (entering class of 96 students)
Total	22,500	29,960

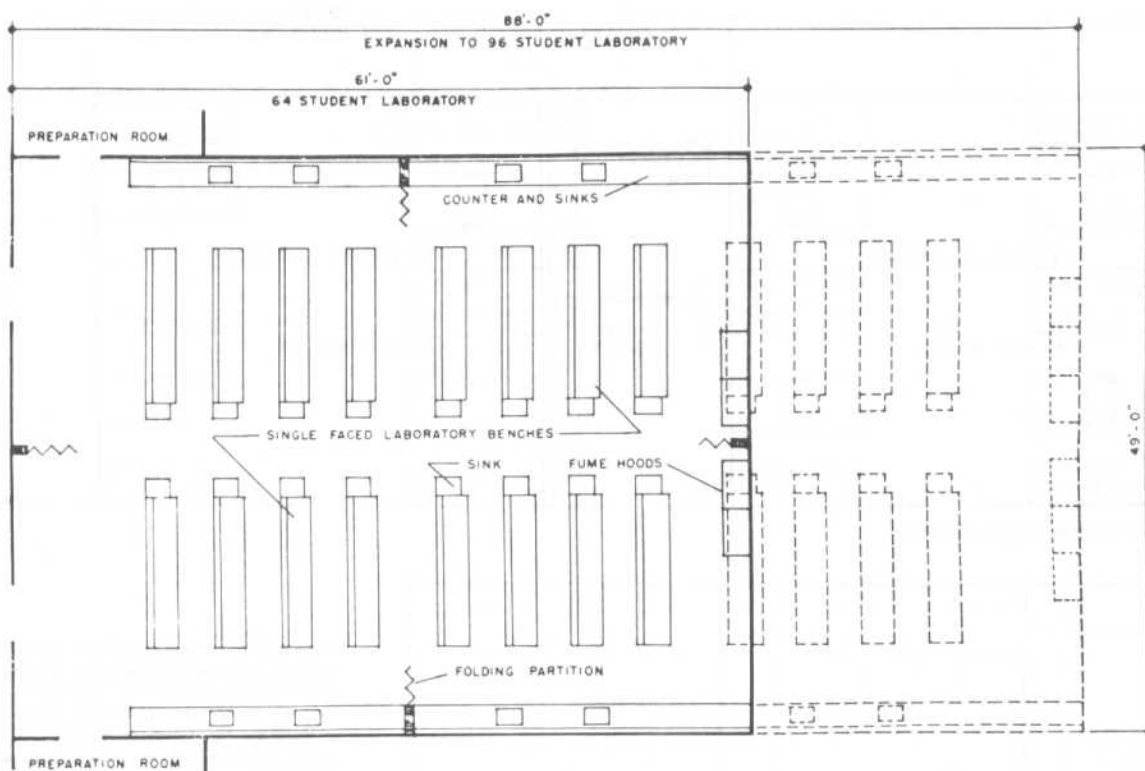

Fig. 4 Layout for a conventional teaching laboratory with single-faced benches.

Fig. 5 Layout for a conventional teaching laboratory with double-faced benches.

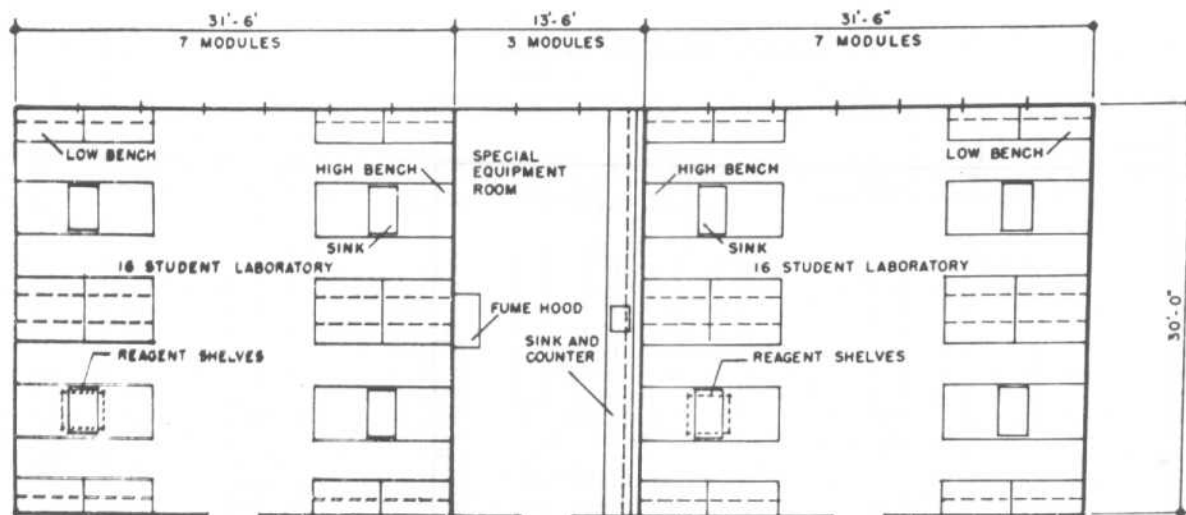

Fig. 6 Layout for multidiscipline laboratories.

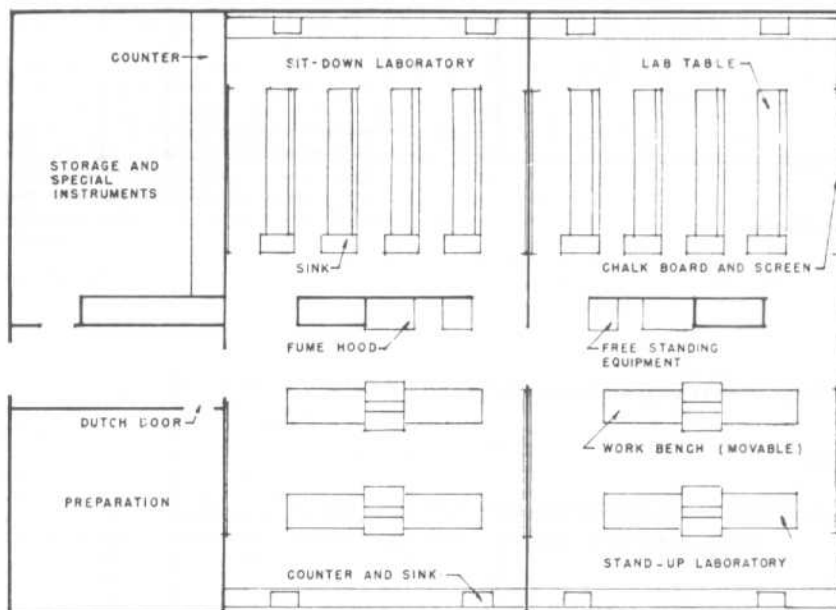

Fig. 7 Floor plan for multidiscipline laboratories.

Additional unassigned conference rooms sized to accommodate 20 persons may be provided in the basic science facilities for use by unscheduled groups.

Basic Science Departments

Anatomy Figure 8 shows a space diagram for a minimum department of anatomy. Table 8 provides a list of net areas for an anatomy department.

Dissecting Room. The teaching area for gross anatomy is usually one large room with stand-up height dissecting tables to accommodate all the students in the course. Convenience for faculty and students and proximity of elevator service to be used for transporting cadavers are important considerations in the location. Provisions should be made to prevent viewing of dissection procedures by unauthorized persons. One dissecting table for each four students is usually required.

Tables should be arranged to allow ample work space on all sides. Additional space to accommodate one or two portable tables for use in demonstrations or by special students may be required. If dissecting tables are movable, a folding partition may be installed to provide a screen behind which the tables may be stacked during off-semesters, freeing the room for other uses.

Handwashing facilities for students should be provided in the dissecting room. Surgical scrub-up sinks, three for each sixteen students, with wrist- or foot-action valves or industrial-type fixtures are recommended. Counter units should have reagent ledges, knee spaces, and under-counter drawers and cabinets for storage of student's dissecting equipment and demonstration microscopes. Electrical service outlets for microscope illuminators should be provided. Counter tops should have resilient surfaces.

Wall-mounted x-ray illuminators, one for

each sixteen students, a bank of four to eight, should be located for easy viewing by a group. Chalkboards located for easy viewing by each sixteen-student group should also be provided.

Storage for fixed specimens and models used in demonstrations and for x-ray film should be provided. Cabinets in a connecting area, such as a utility room, may suffice.

The utility room, which may serve as a diener's work room, should have a flushing-rim service sink accessible to the dissecting area. The sink should have flush valve and wrist-operated valves.

Graduate-student dissecting room. It should be adjacent to auxiliary rooms of the medical students' dissecting room. Fixed equipment and mechanical facilities should be similar to those furnished the medical student.

Microneuroanatomy Teaching Laboratory A conventional student teaching laboratory for microanatomy and neuroanatomy instruction usually requires a demonstration area with a table, chalkboard, projection screen, and sit-down laboratory benches to accommodate all the students of either course. Benches should seat four students on the same side to face in the same direction for an unobstructed view of the demonstration area.

Each bench position should have knee space, drawers, and a cabinet for storing slides and microscope case. Water, air, gas, electrical outlets, and vacuum should be provided at each position. Liquid waste receptors in bench tops may be either lead cup sinks or continuous drain troughs with stone end sinks. Bench top material should be resilient and alcohol- and stain-resistant.

In addition to sit-down benches, some stand-up bench space should be provided for each sixteen students. Bulletin boards and tack boards should be provided.

Graduate-student teaching laboratory. It should be adjacent to auxiliary rooms of the medical students' microneuroanatomy teaching laboratory. Fixed equipment and mechanical facilities should be similar to those furnished the medical student.

Gross Neuroanatomy Room. This room is a supplementary teaching area. Usually the area serves also as a departmental storage center for specimens, in which case adjustable shelv-

¹ For total net area for multidiscipline laboratories, see Table 7.
² For central storage areas, see Table 6.

ing for supporting a number of jars of formalin is required.

The demonstration table, located at the center of the room to accommodate four students on each side, is usually provided with a stainless-steel top with raised edge and an integral sink at one end. Lighting should be designed for close observation at tabletop level. Hand-washing facilities, an x-ray film illuminator, and a chalkboard should be provided. Storage for formalin should be considered.

Tissue Staining and Embedding. This unit may be subdivided into a head technician's office, an embedding area, a sectioning and tissue-staining area, and a slide storage-and-issue area with access to the teaching laboratory, preferably by way of a dutch door for issuing slides and materials.

In the embedding room small tissue specimens are prepared, processed through a number of solutions by hand or in an automatic tissue-processing machine, then embedded in small cubes of paraffin or celloidin. Preparing the specimens requires the use of a refrigerator

for gross tissue storage and a sit-down counter with sink.

For processing specimens and mixing solutions, a stand-up counter with sink, under-counter cabinets for equipment, and wall cabinets for chemicals and reagents are usually sufficient. For embedding procedures, an island bench of stand-up height with paraffin oven at or near one end should be provided.

Cabinets with drawers for paraffin molds and mounting blocks and for filing embeddings in frequent use should be provided. A storage room for embeddings and for fixed gross tissue specimens not frequently used should be provided in the general storage area of the building. Glazed partitions may be installed to separate sectioning and mounting activities from the staining procedures.

Sectioning and mounting activities require sit-down counters with knee space and drawers for storing slides and equipment. Counters for tissue staining and stain mixing should be of sit-down height. Each work position should have a sink, knee space, cabinets for equipment, and chemical storage. For

attaching cover glasses and labels, a sit-down counter with knee space and drawers is satisfactory. Hand-washing facilities should be provided. Counter-top surfaces should be resilient and stain and alcohol resistant.

The slide storage-and-issue area requires standard microscope slide file cabinets, and cabinets for storage of boxed sets of slides.

Microneuro Preparation. To prepare microscope slides used in the neuroanatomy course, a microneuro preparation unit is required similar in design and equipment to the tissue staining and embedding unit for microanatomy. The head technician's office should have access to the unit and to the corridor.

Electron Microscopy. In the preparation room, stand-up and sit-down counters and a fume hood are required. Air, gas, vacuum, and electrical outlets should be available. A refrigerator is necessary for chemical storage. The electron microscope should be located away from electric motors, elevators, fans, and other equipment that may generate vibration and stray magnetic fields. The room should be shielded to minimize dust, and the room should be windowless.

Electron microscopy requires a darkroom next to the microscope room. Table 9 gives the area for an electron microscope suite.

TABLE 9 Net Area for Electron Microscope Suite*

Darkroom	70
Preparation area	280
Entry	30

* See departments of anatomy, microbiology, and pathology.

Cadaver Preparation and Storage. The unit should be so located and designed that no unauthorized persons may enter. Its location relative to the dissecting and autopsy rooms should not require transportation through any public areas. It should be located at grade with a receiving entrance accessible to a low loading platform. Where design permits, the platform may also serve the animal-receiving entrance.

The mortician's work area or *embalming room* should permit working on all sides of the embalming table and handling by stretcher cart, portable lift, or other means. An embalming table with built-in sink at one end is generally preferred. A combination instrument and scrub sink with knee- or foot-operated valve, service sink, and a floor drain should be provided. Floor and wall materials should be washable.

A connected *storage room* for supplies and equipment is necessary. Shower and dressing facilities for use of the mortician should be provided. A *mortician's office* should be adjacent to the area.

Cadaver storage should be adjacent to the embalming room. There are several methods of storing cadavers, some more demanding of space than others. An efficient method is storage on individual tray shelves on both sides of a service aisle. Thirty-five tray positions are usually adequate for a school with a 64-

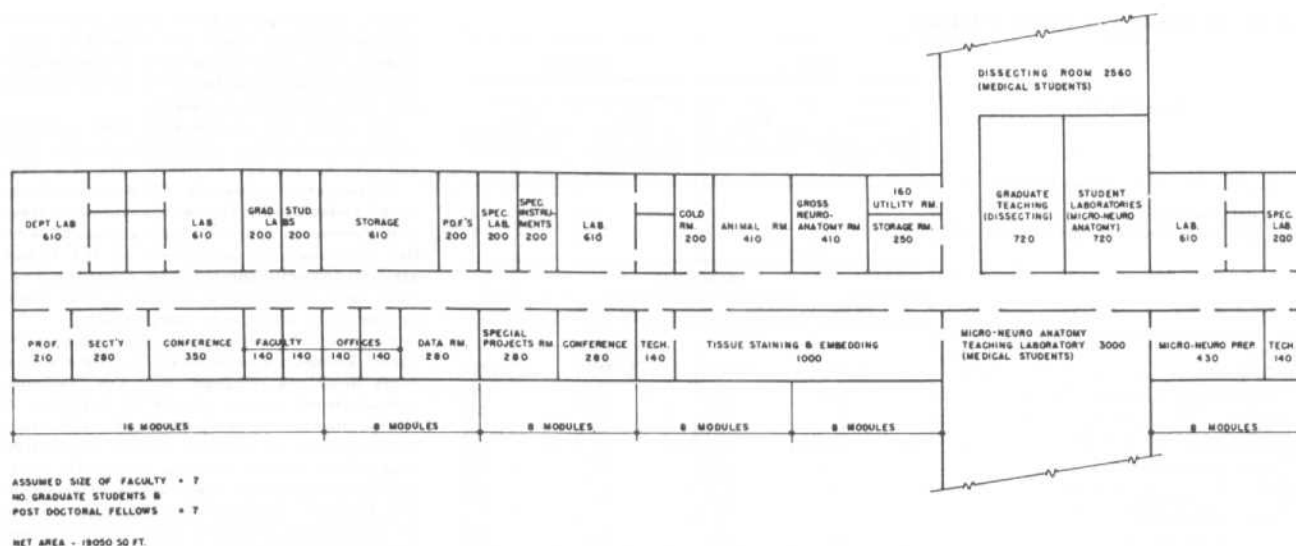

Fig. 8 Diagram for a department of anatomy.

student entering class; provision should be made in the original planning for approximately 60 tray positions to accommodate enrollment increases up to 96 students.

A crematory, if provided, should be located in the cadaver preparation and storage unit.

The department will require storage space for tissue embedments and gross organs. The same type storage as that described for pathology should be provided.

Biochemistry Figure 9 shows a space diagram for a minimum department of biochemistry. Table 10 gives the area for the department for the 64- and 96-student class hypothetical schools.

Teaching Laboratory. The conventional teaching laboratory is similar to those of other basic sciences. Island-type laboratory benches approximately 16 feet long will accommodate eight students, four on either side. The bench should have a stone sink at one or preferably both ends and a continuous drain trough or cup sinks (one for each two students), a continuous reagent shelf, and individual service outlets for each student. Services required are gas, air, vacuum, cold water, and electricity. Bench tops should be stone or acid-resistant composition surfaces.

A large chalkboard, smaller chalkboards for each 16 students, a retractable projection screen, and a bulletin board should be provided. An instructor's table of desk height with knee space, cabinets, cup sink, electrical outlets, cold water, and gas should be provided for demonstration to the class.

The teaching laboratory should be adjacent to auxiliary rooms of the medical student teach-

ing laboratory. Fixed equipment and mechanical facilities should be similar to those furnished the medical student.

Preparation Room. A preparation room adjacent to the teaching laboratory is used for mixing reagents and for storing chemicals and glassware. It may be divided by partitions into alcoves for separating issue, storage, and preparation. These alcoves should have laboratory benches, sinks, and cabinets for use as a research area. The storage of glassware, chemicals, and other stocked items requires adjustable shelving. The issuing area requires cabinets with small drawers and an issue window or door opening into the teaching laboratory.

Glassware Washing and Storage. Commercial glass washing and drying machines are often employed. In addition, a large sink with drainboards is required, with space for glassware carts, a worktable for glassware sorting, and shelves for storage.

Physiology Figure 10 shows a space diagram for a minimum department of physiology. Table 11 gives the net area for a physiology department.

Teaching Laboratory. A conventional teaching laboratory may be used by more than one department. The laboratory described here is a conventional laboratory designed for specific use by the department of physiology. With only minimal additional equipment this laboratory is suitable for pharmacology teaching.

Many animals are used in physiology teaching and stand-up tables 37 in. high with casters to accommodate four students, two on each side, are suggested. A shelf under the top

should be provided as storage space for animal boards. A service island may be provided with gas, electrical, air, and vacuum outlets. Distilled water should be piped into one place in each laboratory or preparation area and carboys should be used at work stations. A floor drain should be installed between each pair of service islands.

A 4-ft fume hood should suffice for eight students. Space for incubators should be considered unless they can be placed on counters.

Chalkboards, a bulletin board, and a retractable projection screen should be furnished similar in size and number to those in other teaching laboratories. Space for an instructor's table at the front of the laboratory is required.

Graduate Student Teaching Laboratory. It should be located adjacent to auxiliary rooms of the teaching laboratory. Fixed equipment and mechanical facilities should be similar to those furnished the medical student.

Student Research Laboratory. Furniture and mechanical facilities may be similar to those of a typical research laboratory.

Equipment Storage. An equipment storage area, adjacent to the teaching laboratory, is needed, as is desk space for a stock clerk and technician. A 31-in.-high counter with gas, air, vacuum, and electrical outlets and cabinets should be installed for testing and preparing equipment. An issue window or door opening into the teaching laboratory is desirable. Space for assembly of equipment to be issued and for glassblowing and soldering should be provided.

Shielded Room. If required by the program, a shielded room distant from obvious electrostatic interference must be provided.

¹ For total net area for multidiscipline laboratories, see Table 7.² Special rooms will vary with type of research.³ For central storage areas, see Table 6.

Audio Room. If an audio room is provided, it should consist of a test room and a control room with a triple-glazed clear-glass observation window between and with acoustical treatment, including reduction of floor vibration.

The test room should have a microphone and a speaker cabinet. The control room should have a sit-down counter with cabinets located on the observation window side.

Physio-optics Room. If the student curriculum includes exercises in physio-optics, a special room will be needed with 20-ft separation between the subject and the vision chart. A sink for hand washing and a sit-down counter for recording are necessary.

Treadmill and Gas Analysis. A room close to the laboratory is preferable. The room should also contain a cot and table for recording.

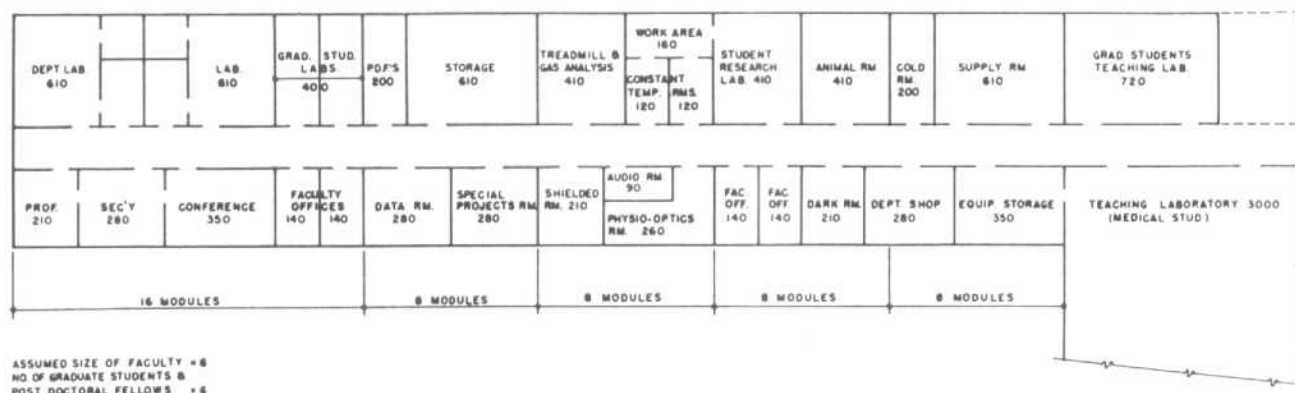

Supply Room. This room should be near the teaching laboratory. Shelving and racks for volatile solvent storage should be within a fire-resistant closet off the mixing and issue areas. Counter tops, 37 in. high, with gas, air, vacuum, and electrical outlets, cabinets with varying sized drawers, and a sink are required for mixing solutions and preparations for student use. Glassware washing and storage require a large sink, drainboards, provision for distilled water, and base cabinets for glassware. An issue window is suggested. Space should be allocated for solution carts and assembly of materials to be issued. A head technician's office may be required depending on the quantity of material handled.

Department Shop. A minimum machine shop should contain a drill press, a metal lathe, a milling machine, and wood and metal bandsaws. A workbench, stock racks, and tool bin are required.

In the electronics area, a sit-down work counter with electrical outlets of appropriate voltages, drawers, and locked storage cabinets for electronic equipment and space to bring in floor-mounted equipment for testing will be required. Noise and vibration associated with technical shops should be considered in their relation to other areas.

Constant Temperature Rooms. Constant-temperature rooms should have access to the corridor and to a work area. Doors from the corridor should accommodate beds or animal

racks. Floor and wall surfaces should be similar to those suggested for animal quarters.

The work area associated with these rooms should have 31-in.-high work counters, a sink, and gas, air, vacuum, and electrical outlets.

Microbiology Figure 11 shows a space diagram for a minimum department of microbiology. The net area for a microbiology department is given in Table 12.

Teaching Laboratory. The conventional teaching laboratory is usually designed to accommodate the second-year class. Satisfactory results can be obtained with the use of an island-type laboratory bench to position four students all on the same side facing demonstrations.

Laboratory benches may be 31 in. high for sitdown work with microscopes. Each student should have knee space, drawers for supplies, and a cabinet for microscope storage. Bench service outlets should be water, gas, air, vacuum, and electrical for each position. A cup sink at each position, or continuous drain trough, and a shelf for storing bottles above are required. Bench tops should be resilient and stainproof.

In addition to island benches, it is desirable to have counters 37 in. high, with reagent shelves equipped with gas, air, vacuum, electrical outlets, and sinks with wrist-action valves for hand washing.

A chalkboard, a bulletin board, a retractable projection screen, and space for the instructor's desk at the front of the laboratory are required. Space in the teaching laboratory may be required for incubators and refrigerators. One domestic refrigerator per sixteen students and one stationary incubator per eight students should be provided. A stationary centrifuge, one per sixteen students, may be provided depending on the curriculum.

Facilities should be available to maintain and observe such small animals as rabbits, guinea pigs, and mice close to the teaching laboratories.

Graduate Student Teaching Laboratory. It should be adjacent to auxiliary rooms of the teaching laboratory. Fixed equipment and mechanical facilities should be similar to those furnished the medical student.

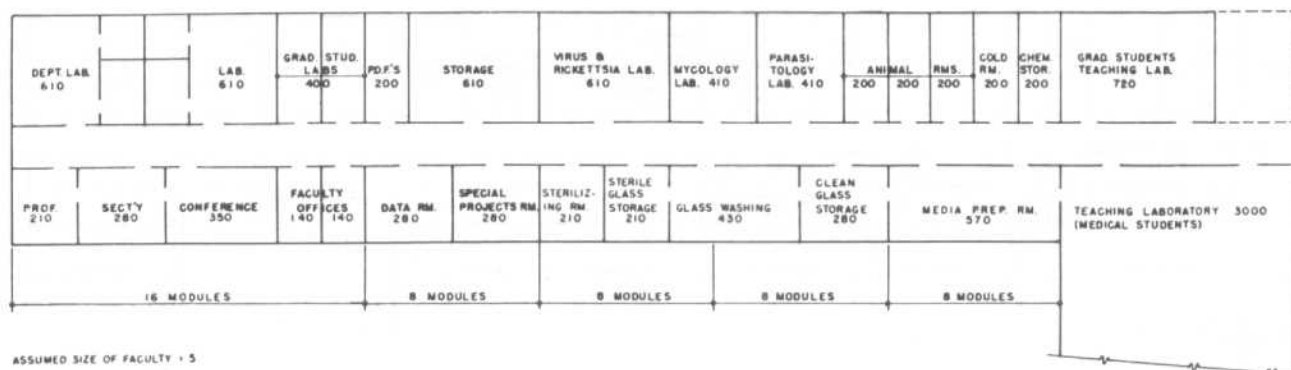

Research Laboratories The microbiology

² For central storage areas, see Table 6.

research laboratories will, in many instances, be similar in equipment and design to laboratories in other basic sciences. However, laboratories used for bacteriological and virus research have additional requirements. Glassware of an unusually large size is often used. One sink in each laboratory should be sized to wash this glassware.

Separate animal rooms are provided in the microbiology department to prevent cross-contamination. If highly contagious material is to be handled, a vestibule may be needed at the entrance to microbiology animal rooms to permit the attendant to change clothes and shoes to reduce infection and cross-contamination.

Electron Microscopy. Facilities for this purpose would be similar to those described for the department of anatomy.

Media Preparation. Media preparation areas should be adjacent to teaching areas and designed to eliminate through traffic to prevent drafts and the introduction of contaminating organisms. A media kitchen requires a range, or portable hot plates on a counter 37 in. high, for cooking the material. Counter-top sinks and cabinets with drawers ranging in width from 6 in. to 2 ft 6 in. and wall cabinets with shelves for storage are desirable. Counters should have air, gas, vacuum, and electrical outlets. Distilled water should be piped to one location over a sink and distributed in carboys.

After the unsterile liquid culture media has been prepared in bulk quantities, it is dispensed into test tubes or plates. This requires counter space similar to the media kitchen, including wall and base cabinets and service outlets.

An autoclave is required for sterilizing prepared culture media after it is poured into previously sterilized petri dishes. A flushing-rim sink near the autoclave is desirable for disposal of spoiled media.

The issue room will contain glassware and equipment storage, shelving and cabinets for glassware and equipment, and an issue window opening into the laboratory.

Glassware Washing and Storage. If this is to be done as a central unit for the department, it should be divided into sterilizing, sterile storage, glassware washing, and clean glass storage.

An autoclave to sterilize glassware prior to washing, a sink and drainboard area, and space for chemical jars and for soaking extra dirty glassware are required. Commercial glass

MEDICAL SCHOOLS

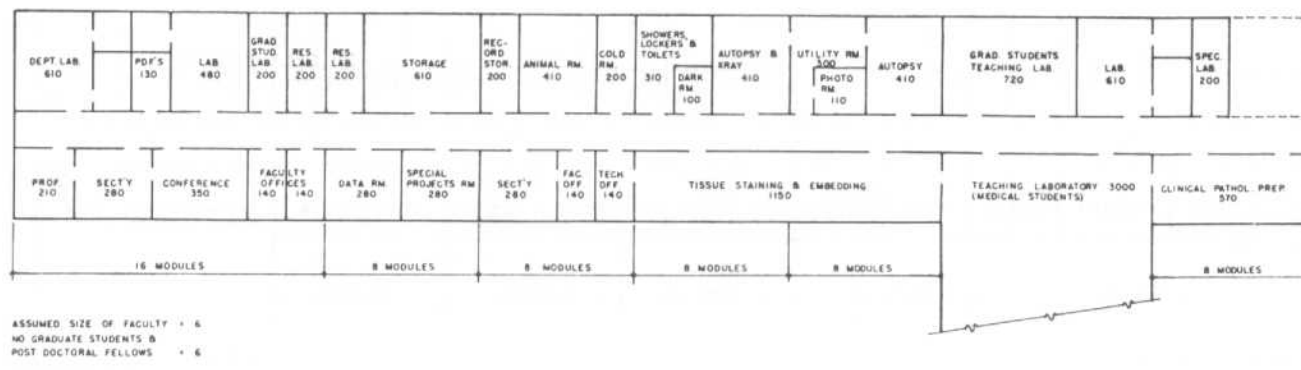

Fig. 12 Diagram for a department of pathology.

washers and dryers may be employed and space for these should be provided beside the sink. Space should be available at sink and washer area for glassware and petri dish carts and cart storage.

Storage areas should be furnished with adjustable shelving, as some glassware may be exceptionally long or high. An issue window or door from sterile storage to corridor should be provided.

Chemical Storage. Bulk storage of chemicals should be provided for in basement areas.

Pathology Figure 12 shows a space diagram for a minimum department of pathology. Table 13 gives the net area for a pathology department.

Teaching Laboratory. A conventional teaching laboratory similar to that described for micro- and neuroanatomy is usually adequate for teaching the second-year pathology course.

Graduate Student Teaching Laboratories. These should be adjacent to auxiliary rooms of the medical students' pathology teaching laboratory.

Tissue Staining and Embedding, Technician's Office. A unit similar in design and equipment to the tissue staining and embedding unit described for microanatomy should be provided.

Clinical Pathology Preparation Unit. This unit usually has a head technician's office and a preparation room with direct access to the teaching laboratory, preferably by a dutch door. For preparing some types of specimens as well as stains and reagents for direct issue, a stand-up counter 37 in. high is desirable. For other types of specimens, particularly those such as blood and bone marrow, a sit-down counter 31 in. high is more convenient. Both counters should have reagent shelves, counter-top sinks, air, gas, vacuum, and electrical service outlets, knee spaces, cabinets for storing equipment and chemicals and reagents. Work surfaces should be alcohol- and stain-resistant and resilient to minimize glass breakage. A refrigerator for storage of clinical material and a lavatory with wrist-action valves for handwashing are necessary. Space for parking a specimen cart should be provided.

Autopsy Room. This should be located convenient both to the teaching hospital and to the pathology department and arranged so as to prevent unnecessary contact of unauthorized persons with autopsy procedures. If the basic science building is separated from the teaching hospital, autopsy facilities should

¹ For total net area for multidiscipline laboratories, see Table 7.

² For central storage areas, see Table 6.

be located in the hospital to avoid transporting bodies from one building to another.

Each autopsy room should be equipped with a scrub-up sink with knee- or foot-action valve; a sink with drainboards, cold-water manifold, and gas and electrical service outlets; an adjacent work counter with drawers and cabinets for storage of supplies; a flushing-rim clinical sink; wall cabinets with adjustable shelves

and glazed doors for storing instruments; a wall-mounted four-bank x-ray film illuminator; and a chalkboard. An instrument sterilizer and a storage cabinet for fixed specimens should also be provided if they are not available in an adjoining utility or clean-up room.

Water and ac electrical service outlets with waterproof caps are required. A table with downdraft top for removal of contamination

and odors directly at their source, with an integral sink at one end of the top, and service outlets, is generally preferred. Provision should be made for foot-operated dictation equipment. A ceiling-mounted 35-mm. still camera should be located over the table for *in situ* photographs during the autopsy. The same mount may provide for TV to remote monitors.

Space to accommodate a portable observation stand opposite the table for convenient viewing of autopsy procedures by students and house staff should be provided.

Floor and walls should be of water-resistant material, and a floor drain should be installed.

Autopsy and X-Ray Room. A mobile x-ray machine should be provided. X-ray protection should be in accordance with the recommendations of the applicable handbooks of the National Bureau of Standards.

Utility and Clean-up Room. This room should be located between two autopsy rooms with direct access to each and to the corridor. Equipment for this area includes a sink with drainboard; a flushing-rim service sink; provisions for storage of glass jars, formalin, and alcohol; wall cabinets for fixed specimen storage; and an instrument washer-sterilizer unless provided in each autopsy room.

Photo Room. The photo room should adjoin the autopsy room.

Fixed equipment in a photo room usually includes a stand-up counter with sink and electrical outlets, a cabinet for instruments and supplies, and shelves for photographic accessories.

For photographing gross specimens, a 3-ft-square light box is used. Electric outlets for table and floodlamps should be 30 amperes.

Darkroom. Wet and dry areas of the darkroom should be separated. A refrigerator for storing color film should be provided, and water supply at all processing sinks is required.

Bench tops should be chemically inert, watertight, and wear resistant. Floor surfaces should be waterproof, resistant to chemicals, resilient for foot comfort, and not slippery when wet.

Cold Room. A cold room separate from the research cold room but adjacent to the autopsy areas for holding tissue and organs for later study is required. A deep-freeze unit and adjustable metal shelving may be provided for preservation of fresh gross material for class use. Stand-up counters with sinks and air, vacuum, and electrical service outlets are required. Floor surface should be smooth, waterproof, and wear resistant.

MEDICAL SCHOOLS

A separate room for storing gross pathological specimens should be provided.

Gross Pathology Conference Rooms. A stand-up table with sink at one end and down-draft top similar to that described for the gross neuroanatomy room is appropriate. Other equipment includes adjustable shelving, x-ray film illuminators, bulletin board, and scrub sink with knee or foot controls. Where possible, this area should have direct access to the cold room.

Dictating Room. This is a small room equipped with desk and equipment for writing or dictating autopsy records.

Record Storage. Open-faced shelving with shelf dividers designed for vertical stacking of the records with a reference table and chairs should be provided. A storage room for records of less frequent reference should be provided in basement storage.

The pathology department requires areas for storage of embeddings, fixed tissue, gross organs, microscope slides, and protocol records not in frequent use. Tissue in solution is kept in glass jars, paraffin sealed, and stored on wood shelving designed for jar height.

Microscope slides are usually contained in metal slide files, and this area should be separated from areas where formalin vapors are present. Protocol records are often bound and placed on shelving or in legal-size file cabinets.

Pharmacology Figure 13 shows a space diagram for a minimum department of pharmacology. Net area for a pharmacology department is given in Table 14.

Teaching Laboratory. The conventional pharmacology teaching laboratory may be similar to the physiology teaching laboratory.

Graduate Student Teaching Laboratory. This should be adjacent to auxiliary rooms of the medical student teaching laboratory. Fixed equipment and mechanical facilities should be

similar to those furnished the medical student.

Student Research Laboratory. A student research laboratory, if provided, should contain facilities similar to those in typical pharmacology research laboratories. Where possible, it should be located within the teaching area but adjacent to research areas.

Glassware Washing and Storage. Glassware washing and storage facilities similar to those indicated for the biochemistry department are adequate in the pharmacology department; they should be located near the teaching laboratory.

Preparation Room. This should be adjacent to the pharmacology teaching laboratory.

Anesthesia Storage. An anesthesia storage room should be provided with cylinder storage racks to lock cylinders in an upright position and shelving for pressure gauges and other anesthetic equipment. Space at ground level should be provided for bulk storage of cylinders.

Supply Room. A supply room in pharmacology may be divided into two areas: one for instruments and general supplies and the other for chemicals used in research.

Some instruments require floor space while others should be placed on shelving. A desk-high counter with drawers and file cabinet is needed. Since some instruments may be used here, electrical outlets should be provided.

If narcotics are to be stored, a built-in safe should be provided.

Space must be provided for the care of animals used in experimental work in pharmacology.

A summary of space estimates for all basic science facilities is given in Table 15.

Clinical Science Facilities

The departments generally include internal medicine, surgery, pediatrics, obstetrics and gynecology, psychiatry, preventive medicine,

and radiology. Pathology, although usually considered a basic science department, nevertheless has many of the characteristics of a clinical department and, therefore, functionally and structurally, usually bridges both.

Space diagrams for the departments of medicine, surgery, pediatrics, obstetrics-gynecology, psychiatry, and preventive medicine are shown in Figs. 14 through 19 for a hypothetical school with an entering class of 64 students (60 in the third and fourth year). Tables 16 through 21 give the net area for a minimum facility for each clinical department for hypothetical schools with entering classes of 64 and 96 students. Table 22 gives a summary of space estimates for all clinical science departments.

For convenience of operation, clinical department facilities should be located between, and connecting with, the basic science building and the teaching hospital. This allows for joint use of teaching, research, and supporting facilities provided in the basic science building and makes it convenient for the medical staff to take care of their hospital responsibilities. Departments should be located on the same floor or floors as the patient-care units they serve.

Research facilities in the form of laboratories should be provided for each department member.

Teaching activities of all departments will be carried out, for the most part, in common lecture rooms, on the wards of the hospital, and in the outpatient department.

Medicine The department of medicine consists of physicians specializing in internal medicine and includes the subspecialties of allergy, cardiology, dermatology, gastroenterology, hematology, infectious diseases and immunology, metabolism, neurology, and pulmonary diseases. The members of the department will have responsibility for the care of hospitalized patients, for ambulatory patients in the medical clinics of the outpatient department, and for medical consultations on patients under the care of other clinical services. They will have major teaching duties for second-, third-, and fourth-year medical students, interns, residents, and clinical fellows.

Surgery The department of surgery consists of physicians specializing in general surgery or in one of the surgical specialties, which include anesthesiology, ophthalmology, otolaryngology, orthopedics, neurosurgery, plastic surgery, thoracic surgery, and urology. The members of this department will have responsibility for the care of patients who are hospitalized on the surgical service; who visit the surgical clinics of the outpatient department; and who require surgical consultation while on some other service. Often the emergency service of a hospital is under the direction of the department of surgery, as may be the professional aspects of disaster planning. The department of surgery will have teaching responsibilities for second-, third-, and fourth-year medical students, interns, residents, and surgical fellows. Each full-time member of the department may be expected to engage in research.

Pediatrics The department of pediatrics consists of physicians specializing in the developmental aspects of physiological processes and expressions of disease. They are as concerned about the long-term health effects of early disease and with their prevention, as with the immediate care of infants and children. In most

MEDICAL SCHOOLS

university hospitals, the age range extends to the fourteenth or sixteenth year. Pediatrics is a nonsurgical specialty. Consequently, surgery on patients in the pediatrics age is generally handled by the department of surgery. As in internal medicine, a number of subspecialties generally based on organ systems such as cardiology, neurology, and endocrinology are usually represented in the department of pediatrics.

The general requirements for departmental offices, teaching spaces, and laboratories are the same in pediatrics as in other clinical departments. Teaching is generally concentrated within one or both of the last two clinical years. In addition, there are teaching responsibilities for interns, residents, and postdoctoral fellows in pediatric training.

Obstetrics and Gynecology Obstetrics concerns itself with the processes of conception, gestation, and delivery in women, whereas gynecology deals with the specific diseases of the female reproductive tract.

Requirements of the department of obstetrics and gynecology for administrative office, teaching and research space are not essentially different from those of any other clinical department.

TABLE 22 Summary of Space Estimates for Clinical Science Facilities for a Hypothetical Four-Year Medical School*

Type of facility	School A (entering class of 64 students)	School B (entering class of 96 students)

Radiology‡.....		
Anesthesiology‡.....		
Pathology§.....		

* This table does not include the supporting facilities which are a necessary part of both the basic science and clinical science facilities.

† To compute the gross area, it is estimated that 85 percent of the total gross area is available as usable space, while the remaining 35 percent will provide space for exterior walls, partitions, corridors, stairs, elevators, and duct ways and chases for mechanical and electrical requirements.

‡ In the teaching hospital.

§ Preclinical pathology is taught in the basic science facilities. Space for clinical pathology may be provided in the teaching hospital.

ical department. Usually this department confines its teaching activities to students in one or both of the third and fourth years. Teaching activities may expand to include such courses as reproductive biology. In addition, there are teaching responsibilities for residents and fellows. Interns are generally not assigned to this service except as part of a rotating program. Student groups may be smaller than in some services and, therefore, teaching space should be sized accordingly.

Psychiatry The department of psychiatry consists of specialists concerned with the functions and disfunctions of the mind and emotions.

Offices for members of the department of psychiatry may be used for somewhat different purposes than staff offices of other clinical departments. For example, not only do psychiatrists use their offices for desk work, study, and conferences with students and others, but they may also use them as interview rooms for psychiatric patients. Clearly, this will have an effect upon the design of the psychiatric departmental office suite in that it may be necessary to incorporate waiting rooms for patients and space for the administrative control of patients in addition to the usual departmental administrative space, teaching space, conference rooms, and reference libraries.

Consultation rooms connected by a one-way viewing screen or TV with an adjoining observation area are frequently required.

In general, studies involving psychiatric patients are best carried out in research facilities associated with the psychiatric bed area, and laboratory studies not involving patients are best carried out in departmental research laboratories.

Preventive Medicine In general, however, the discipline of preventive medicine comprises physicians who are concerned with the natural history of disease and the factors in the environment which have an effect upon morbidity and mortality. They are interested in reducing the incidence of avoidable disease and premature death through control of those factors which may contribute to disability and incapacity.

There is usually a close relationship between the staffs of pediatrics, medicine, obstetrics-gynecology, psychiatry, and preventive medicine, and this should be borne in mind in the location and assignment of office space.

SELECTING THE SITE

Preferred Locations

Dental educators generally prefer certain locations for a dental school. The obvious choice, a university campus, has impressive advantages. It offers students and faculty a richer cultural life and often a more pleasant environment. Adequate housing and student facilities may be more readily available than in other locations. If the university also has a medical school on campus, students and faculty can enjoy a close association with other health professions.

Location in a health center is also advantageous, since it offers access to a complex of health facilities and provides day-to-day opportunity for close cooperation between the health professions. A metropolitan location generally assures the school an ample supply of patients for teaching clinics.

The Site Itself

Topography and Dimensions. High ground with natural drainage is desirable, but the elevation should not be so high that approach on foot is difficult. A patient entrance at ground level and a service drive to the basement area should be feasible. A gently sloping lot has advantages, since it offers entrances on two levels; traffic in and out of the building is automatically divided between them, and the movement of people and supplies can more easily be diverted over separate routes within the building. The site selected should be of sufficient size to permit later expansion.

Where land costs are favorable and where parking facilities are planned, a building site covering a minimum of 10 to 12 acres is advisable.

Utilities. Sewerage, water, electricity, telephone, and gas must be available on the site or be extendible to it at reasonable cost. Utilities must also have adequate capacity.

Transportation and Parking. Convenient public transportation is a necessity. Runs should be frequent, with adequate peak-hour service. Good public transportation materially reduces the parking problem. It also makes it easier for the school to secure and retain service and clerical employees. Even with good public transportation, first-class roads should connect the school directly with local traffic arteries.

The site should permit adequate parking areas for students, faculty, and patients. Generally, one parking place for each full-time faculty member and one for every two part-time members is advisable. A site in a suburban area should also allow two parking places per entering class student (ECS) for students, if possible, and another two places per ECS for clinic patients.

In determining how much land will be needed for parking, allow 130 cars per acre (for 45°

parking) as a guide if parking lots are to be used. Parking lots, however, are likely to become desirable building sites, and multilevel garages or underground parking may prove a more permanent solution to the parking problem.

SPACE RELATIONSHIPS

The Effect of Traffic Patterns

The arrangement of the many elements of a school is determined largely by the movement of students, faculty, patients, and materials. **Clinics.** The most common and effective way of reducing traffic within the school is by physical separation of the clinical facilities from the remainder of the school. Staffed by a separate faculty and visited daily by large numbers of patients whose presence elsewhere in the school could be disruptive, the clinical facilities are logically a physical entity. For this reason, physical separation will continue to be advisable even though efforts to break down the rigid separation which exists between the clinical and basic science teaching programs are successful.

However, if they are successful, there probably will be a need to locate certain clinical areas so that students can move between the clinics and the basic science areas without disturbing the clinical routine. Planning committees should therefore consider the possible

implications of this change for traffic patterns within the school.

Basic Science and Preclinical Laboratories. The activities of freshmen and sophomores are largely confined to these areas; by locating them in reasonable proximity, with other facilities used by these students nearby, traffic within the school could be materially reduced. However, since laboratory sessions are normally scheduled for a full half day, with students shifting between laboratories only once a day, locating these areas on separate floors or in separate wings may well resolve a particular school's problems of space arrangement.

A Design which Controls Traffic Flow

Figure 1 is a space diagram showing the relationships between and within the clinical and preclinical dental science areas of a school which will locate its basic science facilities in another wing or on another floor.

All student facilities are located close to their major areas of activity. Note the proximity of student lounges and locker rooms to the teaching facilities used by the students. Freshmen and sophomore locker rooms are adjacent to the preclinical laboratories, while locker rooms for junior and seniors are close to the clinic. Locker rooms for both groups adjoin the student lounge and bookstore and are located near the student entrance. Lecture rooms, used by both preclinical and clinical students, are readily accessible from all student areas.

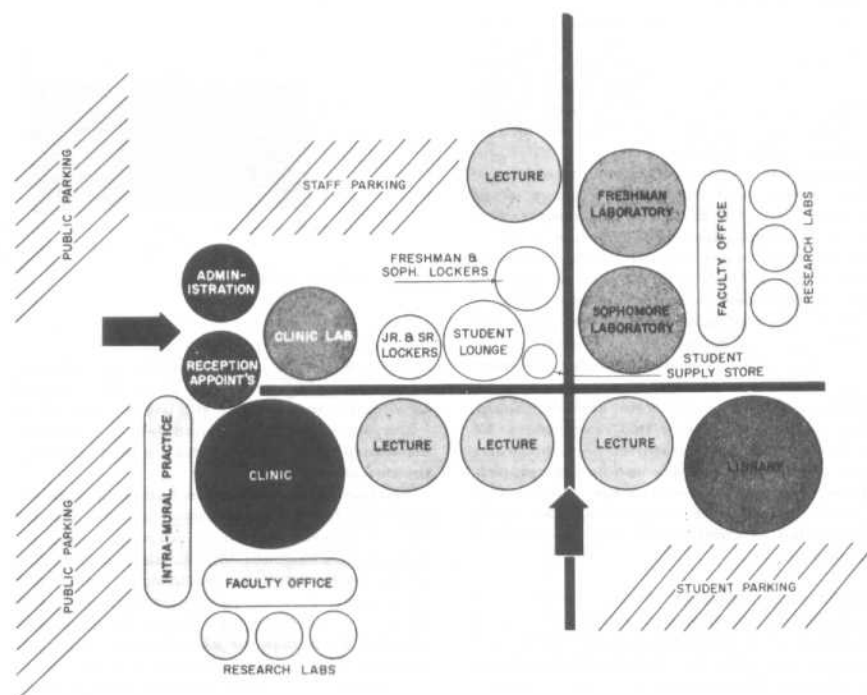

Fig. 1 Space relationships: preclinical and clinical dental science areas.

DENTAL SCHOOLS

The need for a location as free of vibration as possible makes the basement the preferred site for the electron microscope suite, for example, though this location is seldom convenient for users of the laboratory. Facilities which will be used after normal school hours—auditorium, libraries, and study areas—provide another example. Ideally, they should be located so that they can be left open after the remainder of the school is locked.

THE PHYSICAL PLANT: DESIGN AND STRUCTURE

Modular Planning for Flexibility and Efficient Use of Space

Modular planning is particularly adaptable to the design of schools, hospitals, and other buildings in which repetitive elements lend themselves to the systematic and uniform spacing of certain structural features. The module should be a multiple of the basic 4-in. module recommended by the American Standards Association Project A62.

Many building components are prefabricated on this basis, and the floor plans in this section are based on modular design, using a module of 4 ft 8 in.

In Laboratory and Office Planning In the dental school, modular design is particularly applicable to the planning of research laboratories and offices. Figure 2 shows a section of a typical basic science laboratory based on the 4-ft 8-in. module. It is a two-module laboratory, approximately 9 ft in width. When allowances are made for the equipment and laboratory benches extending into the room from the wall, the two-module unit is the smallest size practical but yet adequate for its function.

Examples of Modular Planning When modular planning of areas is combined with modular planning of utilities, various combinations of offices, laboratories, and storage space are practical. (See Fig. 3.)

Figure 3b is a sectional drawing of a research floor of a school. Figure 3c is a partial plan of the corridor wall. Columns are located at every fifth module. Vertical utility shafts, which supply the laboratories with water, drainage, gas, and other utilities, are located at every fourth module.

Figure 3a shows the arrangements of laboratories, office, and equipment storage areas possible with this design. For example, if a series of laboratories of four-module width is desired, either index A or B can be followed. Index A has the laboratory bench at the side walls, while index B shows a center island or peninsula type of laboratory. If an office and equipment room is desired with each laboratory, these can be substituted for alternate laboratories.

Indexes C and D illustrate smaller laboratories suitable for one or two researchers. Index C is a series of laboratories only, and index D is a combination of two-module laboratories, offices, and equipment storage rooms. One or more four-module laboratories can easily be provided in combination with two-module laboratories.

Advantages and Limitations Modular design can be applied to structures in which utilities are located at or in the exterior walls. It can also be used, and with perhaps greater flexibility, in research laboratories in which a central utility core is utilized. (Fig. 4.)

Fig. 2 Building module.

Modular design provides a basis for determining the width of laboratories and offices. In estimating depth, at least 24 or 25 ft should be allowed. In Figure 18 the bay depth is 28 ft—the equivalent of six modules; a sufficient allowance when utility shafts are located along the corridor wall.

Caution should be used in following modular planning for other elements of the dental school. Where location of columns is important, strict adherence to the selected planning module may result in obstacles in aisles and other areas. This is a particular problem in the clinics, where chair layout may be adversely affected by a lack of coordination with the structural and mechanical features of the building. In the clinic area, modular design is of lesser importance in those plans in which op-

eratories, laboratories, offices, and other small rooms are not located along the exterior walls.

BASIC SCIENCE FACILITIES—IN GENERAL

Few decisions made in the initial stages of programming will have a greater influence on the space and structural requirements of the dental school than those reached in defining the school's teaching and research objectives in the basic sciences.

Departmental Facilities

The head of every department needs a private office with space enough to accommodate small staff or student conferences. An adjoin-

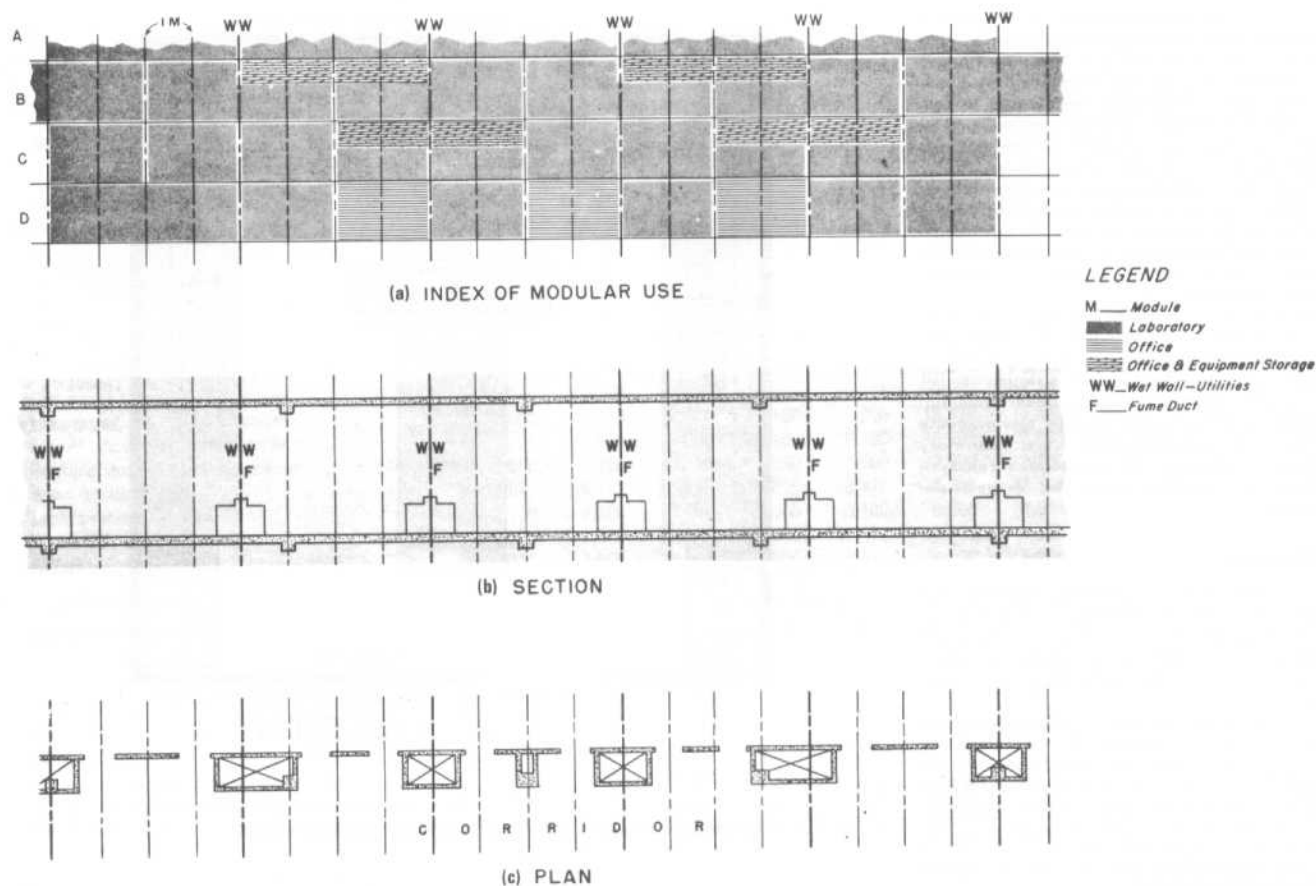

Fig. 3 Modular planning of research areas.

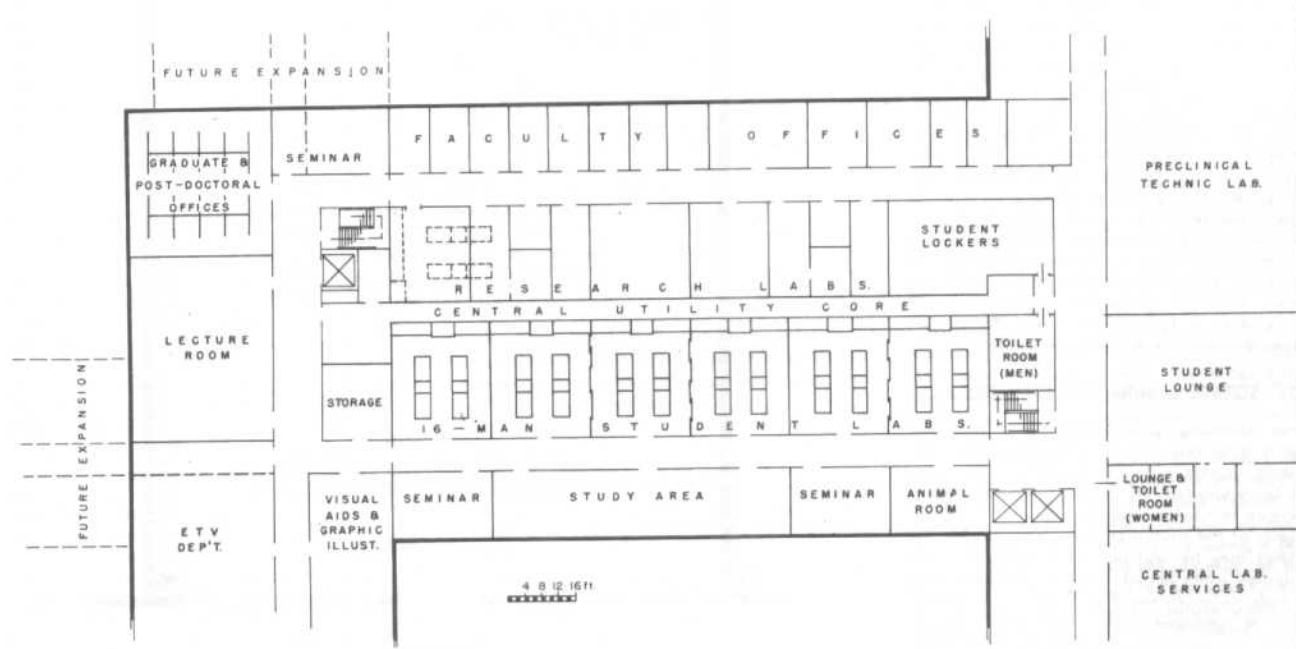

Fig. 4 Plan for a basic science area utilizing a central utility core.

DENTAL SCHOOLS

ing office should be provided for the department secretary. A conference room and a seminar room accommodating a 16-student group should also be provided. In addition to chalkboards and bookshelves, each room should be equipped with or adaptable to the use of slide and film projectors and ETV. Both can be used for staff or student conferences, or for formal but unscheduled classes or seminars. A data processing room for use both by faculty and graduate students is also an advantage. Special equipment need not be elaborate, and may include an adding machine, a calculator, and a typewriter.

A storage room easily accessible to staff offices and research facilities is a major convenience. Properly planned, it can always be converted into office space—a much-needed insurance against eventual overcrowding.

Every full-time faculty member and graduate student will need office and research laboratory space. In addition, an unassigned research laboratory should be considered for each department.

Laboratories

The traditional arrangement for basic science teaching provides a laboratory of class size for every department. This calls for a separate laboratory for anatomy, biochemistry, physiology, microbiology, pathology, and pharmacology.

Considerably less space will be needed for undergraduate teaching if multidiscipline laboratories are used, and dental schools have generally found that more than one discipline can easily be scheduled for a single laboratory. Schools which use integrated systems of instruction or which need to assure a marked degree of flexibility will necessarily plan multidiscipline laboratories.

If they are equipped with movable partitions and four- or eight-man position benches, both departmental and multi-discipline laboratories of class size are easily divided into smaller units to accommodate research projects or small-group teaching. Many educators, however, look with increasing favor on the laboratory designed specifically for the smaller number of students. Figure 5 is a floor plan showing how items of equipment are placed. Sophomore laboratories have no anatomy table but are otherwise similar.

Unit laboratories accommodating a larger number of students and designed for teaching only the basic science disciplines are more widely favored. Figure 6 is a floor plan of a 16-student laboratory in which physiology, biochemistry, and pharmacology are taught. More detailed information on the arrangement and equipment of teaching laboratories, and the special facilities associated with them will be found in a following section. Suggested space allowances are shown in Table 1.

BASIC SCIENCE LABORATORY FACILITIES

Three teaching laboratories—two multidiscipline and one single discipline—are described in this section. Together, the three can accommodate all of the basic laboratory sciences taught in a dental school.

Each of the multidiscipline laboratories described may be laid out as a series of self-contained units accommodating small groups of students, or retained as a class-size laboratory and equipped with folding partitions to permit division of the room into smaller units.

The ancillary and special facilities required by the different disciplines using these labora-

Fig. 5 Layout and equipment of unit laboratory for both basic and preclinical sciences.

tories are generally described, and they are substantially the same whether small-group or class-size laboratories are utilized.

Low-Bench Disciplines

Teaching Laboratory The disciplines which share the low-bench teaching laboratory are those employing microscopy as their principal technique—histology (the microscopic study of normal tissue), pathology (the microscopic study of diseased tissue), and microbiology (the study of microorganisms).

Laboratory Benches and Arrangement. Laboratory benches are usually 30 to 32 in. high to permit students to sit comfortably for long sessions at the microscope. Stools have back rests and adjustable seats. Either single or double-width benches may be used. However, because all students sit along one side of single-width benches, these can be more easily arranged to permit all students to face the demonstration area. A four-position bench is particularly desirable in the class-size laboratory, since it permits the division of the class into groups of 16 or less without splitting the group at any bench. If double benches are used, the eight-position bench is preferred.

Clearances of 3 ft between single-width benches and 4 ft 6 in. between double-width benches are required. Side aisles, center aisle, and main cross aisle should be 6 ft wide.

Work Station at the Bench. Each position at the bench should be at least 42 in. wide to allow both adequate knee space and room for a base cabinet containing drawers for storing slides and supplies and a cupboard for storing a microscope. Water, gas, and electricity should be available at each position. The need for an air outlet is limited, and a vacuum is seldom used. A lead cup sink at each position

(or a bench-long drain trough with a sink at one end) is necessary.

Bench Tops. Bench-top surfacing should be resilient, to minimize slide breakage, as well as stain and alcohol resistant. Bench tops should be as free of joints as possible.

Stand-up Work Areas. Wall counters (37 in. high) are located along the sides of the laboratory area. These provide bench space of stand-up height, where students may set up portable equipment, conduct experiments with animals, or take part in other assigned projects. Counter-top handwashing sinks with knee- or foot-operated valves should be installed and supplied with hot and cold running water. Gas, air, and electricity outlets will also be needed. One set of outlets for every four work stations at the counter is adequate.

Demonstration. The demonstration area should have a table, retractable projection screen, and a chalkboard at least 4 ft high and as long as the supporting wall permits. Additional small chalkboards—3 by 4 ft—should be available throughout the laboratory. At least one for every 16 students should be provided, and all chalkboards should have adequate illumination. A bulletin board is also advisable. Because small-group laboratories easily accommodate demonstrations, no separate areas are needed for this purpose in schools employing the unit arrangement. Each of the small-group laboratories will require its own projection screens, chalkboards, and a bulletin board.

Stationary Equipment. One noncorrosive fume hood should be provided for every 16 students. Stationary centrifuges in the same ratio are desirable for microbiology. Space will be needed for incubators—one for every eight students—and for refrigerators—one for every 16 students.

Ancillary Facilities Each discipline sharing the low-bench teaching laboratory must have certain ancillary facilities available.

Space for the preparation of microscope slides is necessary for any laboratory in which histology and pathology are taught. Preferably, this area consists of two interconnecting rooms. In one, the embedding room, tissue is processed and embedded in paraffin. This room should have two counters, 31 in. in height, one to be used as a workbench for preparing and processing specimens and the other for mixing solutions. Placing a plain worktable at one end of the paraffin oven provides an efficient arrangement for the embedding procedures. For easy access from either side, the worktable should be located near the center of the room. Wall cabinets for storing solutions and other supplies should be provided.

The second room is used for sectioning, staining, and storing the completed slides. Counters 31 in. high and 2 ft wide should be provided in this room. Each work station at the counter should have knee space of sufficient width and a base unit with drawers for storing blank slides. All of the countertops in these slide preparation rooms should be resilient and stain-resistant.

For microbiology, a media preparation room should be provided adjacent to the teaching laboratory. Usually the work of a trained technician, media preparation requires space for several items of equipment, including a range or hot plates for cooking the material, an autoclave for sterilizing test tubes and media, a refrigerator for storage of culture media, and often an incubator for testing the sterility of media prior to use. This area should be dust-free. Wall counters 37 in. high, equipped with base cabinets and air, gas, distilled water and

DENTAL SCHOOLS

electrical outlets, are needed both in the kitchen area and in the area where media are transferred to test tubes. In the latter, burette stands are normally placed on the counter top.

A fairly large area for glassware washing and sterilization should adjoin the teaching laboratory. Commercial glass-washing and drying machines, an autoclave, and often a hot air sterilizer must be accommodated, as well as sink and drainboards, space for storing the carts which carry glassware and Petri dishes to and from the area, and a worktable for glassware storage.

Storage rooms for chemicals, glassware, equipment, and other materials are necessary. Among the items of portable equipment which may be used and will require space for storage are water baths, incubators, and spectrophotometers.

An animal holding room where small animals may be held for observation or experimentation completes the list of the larger ancillary areas required in conjunction with this laboratory.

Special Facilities. Additional facilities which are of special value for research and teaching in the low-bench disciplines include a cold room and electron microscope setup.

The cold room is essentially a refrigerator room. It contains counter space and sink for work that must be done at low temperatures. Safety door latches and warning lights are mandatory features.

An electron microscope unit requires at least three rooms: one to house the microscope itself, another for slide preparation, and a third—a darkroom—for developing, enlarging, and printing electron micrographs.

High-Bench Disciplines

Teaching Laboratory. The disciplines which share the high-bench teaching laboratory are those for which laboratory work requires that the student stand and move about to perform experiments. These include physiology (the study of the process of living organisms), pharmacology (the science of drugs), and biochemistry (the study of the chemical compounds and processes occurring in organisms).

Laboratory Benches and Arrangement. Laboratory benches are usually 37 in. high. Stools of adjustable height are provided. Except for their height, benches may be similar in design and arrangement to those in the low-bench laboratory. The four-position bench has particular merit because much of the work, especially in physiology, consists of special projects undertaken by a team of four students. **Work Station at the Bench.** The student's work station is also similar to that in the low-bench lab. Each station should have a base cabinet with both drawer and cupboard space. Adequate knee room should be provided, even though students stand a good share of the time.

Hot, cold, and distilled water should be available at each bench position. Gas and electricity are also required. In addition, low-voltage direct current and control circuits should be available from a central panel.

Bench Tops. Bench tops should be of stone or of acid-resistant composition stone because of the reagents used in biochemistry.

Sit-down Work Area. Low counters, with resilient counter tops, and under-counter cabinets are placed along one or more of the laboratory walls. Gas, hot and cold water, air, and electric outlets will be needed, and counter-top sinks should be equipped with knee- or foot-operated valves for hand-washing. Stools with adjustable seats should be provided.

Demonstration Area. The demonstration space and equipment are like that of the low-bench lab. In addition, physiology teaching makes extensive use of electric polygraphs and the Van Slyke machines, often to the extent of one to each four students. If the unit laboratory is used, no demonstration area is necessary since each unit can easily accommodate demonstrations.

Stationary Equipment. Fume hoods—one to every 16 students—should be provided. Because flammable and explosive chemicals are used, the hoods should be installed a safe distance from fire exits. Burette stands, approximately 5 ft in length, are used by both biochemistry and pharmacology students. One to every 16 students is an accepted ratio.

Movable Equipment. A great variety of movable equipment may be used. A few movable tables of stand-up height may be required for some of the experiments in pharmacology and physiology involving animals. Table tops are of laminated wood with a stain resistant finish, and a shelf is provided for storing animal boards. In addition, a deep-freeze unit, centrifuges, refrigerators, incubators, and much of the electronic apparatus used in physiology are part of the movable equipment used in the laboratory for which space is required. First aid kits and blankets are necessary, although these generally occupy no floor space but are mounted on the wall.

Ancillary Facilities. Both biochemistry and pharmacology require a preparation room adjacent to the teaching laboratory for mixing reagents and storing chemicals and glassware. Storage and washing facilities are included in this room. Wall counters similar to those in the teaching laboratory and wall cabinets permit this room to be used as a research area during off periods.

Each discipline requires storage and supply areas, some of them special in nature. Special provisions must be made, for example, for storing anesthetics. Although only a limited supply of cylinders holding oxygen or anesthetics should be kept here (additional storage should be allotted at ground level), the storage area should be located along an exterior wall, with floor and ceiling louvers installed to provide gravity ventilation. The room should be locked. For chemical storage areas, fire hazards must be minimized. Narcotics require locked storage. Generally, rooms used to store instruments and equipment should be amply supplied with electrical outlets so that equipment can be used without being removed from the room.

Animal rooms and cold rooms are among the other facilities used regularly in conjunction with the teaching program of the high-bench laboratory.

Special Facilities. Many of the special facilities used for research and teaching in the high-bench disciplines require unusual construction or safety features.

The chromatography room is a biochemistry research laboratory where various processes are employed to separate organic substances. In laboratories where paper or column chromatography is performed, fume hoods capable of exhausting toxic or inflammable vapors are required, and the laboratory must be maintained under negative air pressure to prevent the spread of vapors. Where gas chromatography is used, it must also be possible to seal off the laboratory in the event of fire. Some instruments used in this laboratory depend upon radioactivity as an ionization source; if these

are installed, safeguards must be provided, even though the radioactivity level is low.

In the ultracentrifuge room, another small laboratory often used in biochemistry research, the selection of equipment will largely determine the requirements. Depending upon its anticipated use, the ultracentrifuge may be either electrically powered or air driven. At least part of the housing for this equipment is of heavy armor plate. Additional cooling may be needed in the room to offset heat produced by operation of the equipment.

Constant-temperature rooms, or controlled-temperature rooms, as they are sometimes called, are used to house small animals under constant temperature and humidity conditions. The work area in this room usually consists of 31-in.-high counters, with a sink and outlet for gas, air, and electricity. Space may be needed for counter-top food storage. At least one floor drain will be required so that the room may be completely washed down.

The space allotted for the radioisotope laboratory should be divided into two rooms, the radioisotope laboratory proper (radiochemistry laboratory) and the uptake-measuring room (counting room).

The radiochemistry laboratory is the room where shipments of radioisotopes are received and stored. Here, too, specimens are made ready for examination, and dosages are prepared and administered. Items contaminated with radioisotopes are either cleaned, held for decay of radioactivity, or stored prior to disposition.

In the counting room, the uptake of the radioactive substance is prepared and the radioactive content of specimens is accurately determined. If the counting room is separated from the radiochemistry laboratory by a corridor, the possibility that stored isotopes will interfere with counting can be substantially reduced.

The location of the radioisotope laboratory some distance away from x-ray equipment prevents interference with measurements of radioactivity. The basement is usually the best location, since it simplifies provisions for waste disposal and shielding. In most schools, a basement laboratory will also be convenient to the central animal quarters, and this is highly desirable. If the main radioisotope laboratory is some distance away from these animal quarters, schools may want a separate and specially designed radioisotope laboratory within the animal quarters.

Safety features and special devices are essential to guard against radiation contamination.

Wall shielding is a necessary safeguard against radioactive penetration, and the average building partition will not usually suffice for this purpose. Plastic, wood, or other light material is adequate shielding against beta radiation. Solid concrete or solid brick walls will be necessary for protection against gamma rays.

Interior wall surfaces should always be of a smooth, nonporous material. High-gloss enamel paint is best suited for this purpose. To facilitate decontamination, strippable vinyl plastic or replaceable wall panels are installed near sinks and other critical areas.

The floor in a radioisotope laboratory is usually a concrete slab. The slab must have a protective covering or coating to prevent radioactive contamination from spillage. The floor should always have a heavy wax coating, which will fill cracks and serve as waterproofing. Counter tops should be stainless steel, with splash-back trims. Sinks should be made of

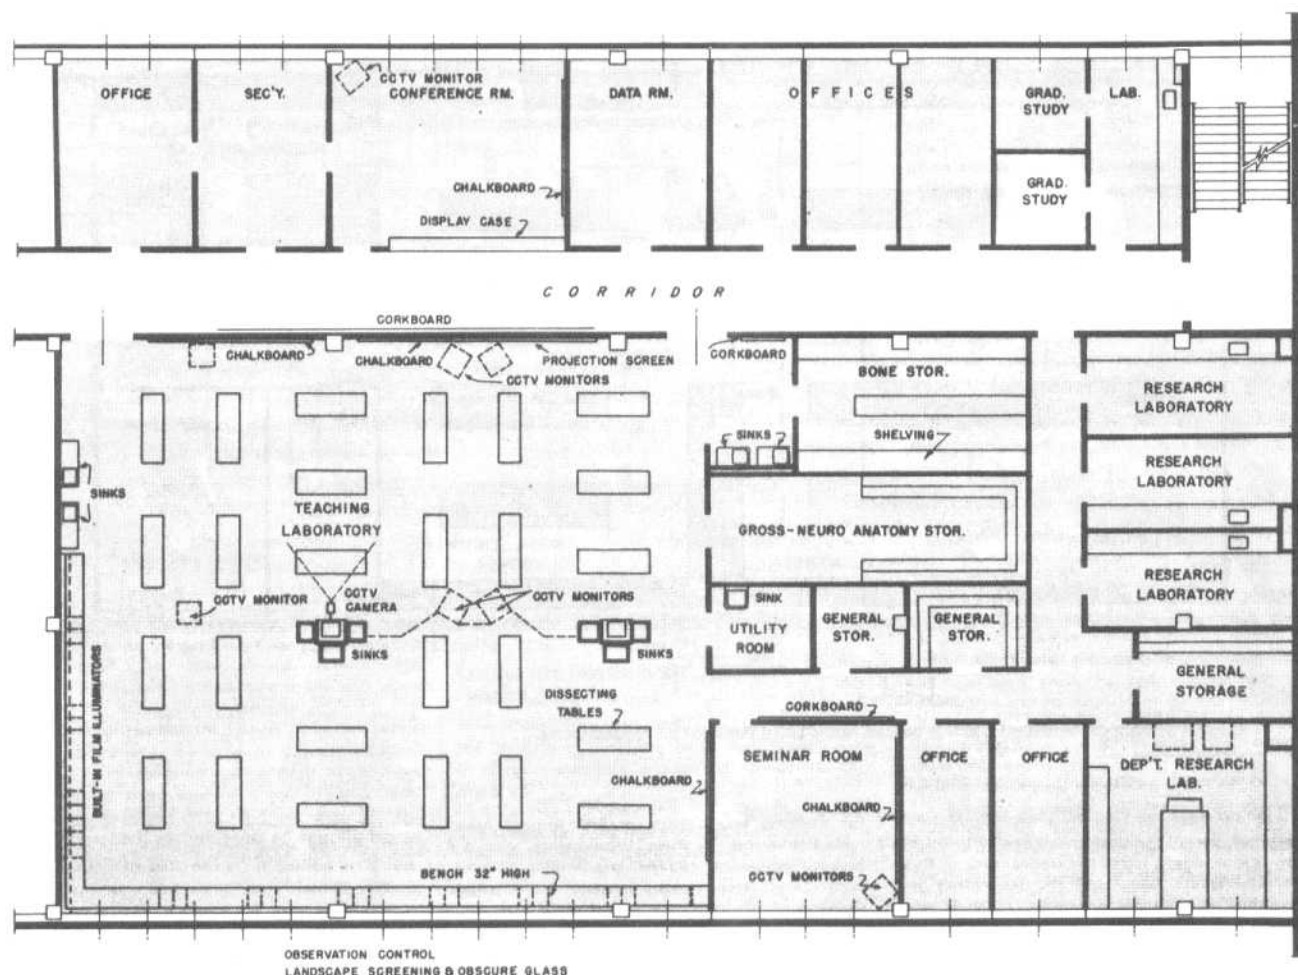

Fig. 7 Layout of anatomy laboratory of class size.

stainless steel and equipped with foot or knee controls. Each sink should have two drain-boards.

Holding tanks must be provided for the collection of large amounts of radioactive materials or small amounts of the more dangerous isotopes.

Special radio-chemical fume hoods are necessary. Because of the dangers of air movement, hoods should never be placed near windows, doors, or ventilators.

A deluge shower will also be needed.

Anatomy

The Dissection Room Dissection tables are the basic laboratory equipment. They are approximately 24 by 78 in. Aisles at the table sides should be 5 ft wide and those at the ends 3 ft 6 in.

Dissection rooms are, as a rule, planned to accommodate full classes. Though class size largely determines room size, space should be allowed to accommodate a few additional tables for use by graduate students and for demonstrations. (See Fig. 7.)

Good table lighting is essential. Often, adjustable lighting fixtures are attached to both sides of each table. If tables are on casters, cleaning of the room will be considerably easier.

The dissection room should be equipped with an adequate number of hand basins.

Round, industrial sinks are a good choice, since they accommodate more students simultaneously than those of standard design. One sink for every four tables is an accepted ratio.

The dissection room should include counter units with drawers and cupboards for storing students' instruments. Storage space should also be provided for such supplies as wood blocks, mallets, arm rests, embalming fluids.

Because of the odor of the preserving fluids, air conditioning with a 100 percent air exhaust should be provided in the dissection room.

As the anatomy dissection room is frequently washed down, durable, waterproof flooring is required. Providing storage space for the dissection tables will make it possible to use the dissection room for other purposes.

Ancillary Facilities

Several additional rooms either near or adjacent to the dissection room are required. Storage space for cadavers must be provided and bone storage space will also be needed. If neuroanatomy is taught in the dissection room, storage for gross specimens must be available, too.

Generally, schools will need sufficient storage capacity for 1.5 cadavers for every four ECS. If the school policy is to hold cadavers for one year prior to use, storage requirements will double. Cadavers are commonly stored in large walk-in refrigerators. Because the

method of preservation and storage affects ancillary space requirements, the system to be used should be determined early in the programming stage, and specifics should be worked out with the aid of qualified consultants.

A room equipped for embalming is often provided, though dental schools with access to medical school facilities will probably need only a minimum of space for this purpose. As for final disposal, cadavers are usually cremated. The dental school can either provide its own crematory for this purpose, share facilities with a medical school, or arrange periodic transfer of cadavers to public facilities for cremation.

Because it should never be necessary to move cadavers through public areas, facilities for cadaver storage and embalming should be as near as possible to the dissection room, and all three should be located at ground level. Wherever practical, loading platforms should open directly into the cadaver storage area to facilitate delivery and removal.

PRECLINICAL FACILITIES

The Preclinical Laboratory The preclinical laboratory is designed to accommodate the entire class of freshman or sophomore students in a single session. (See Fig. 8.)

Though it is not often so-called, the pre-

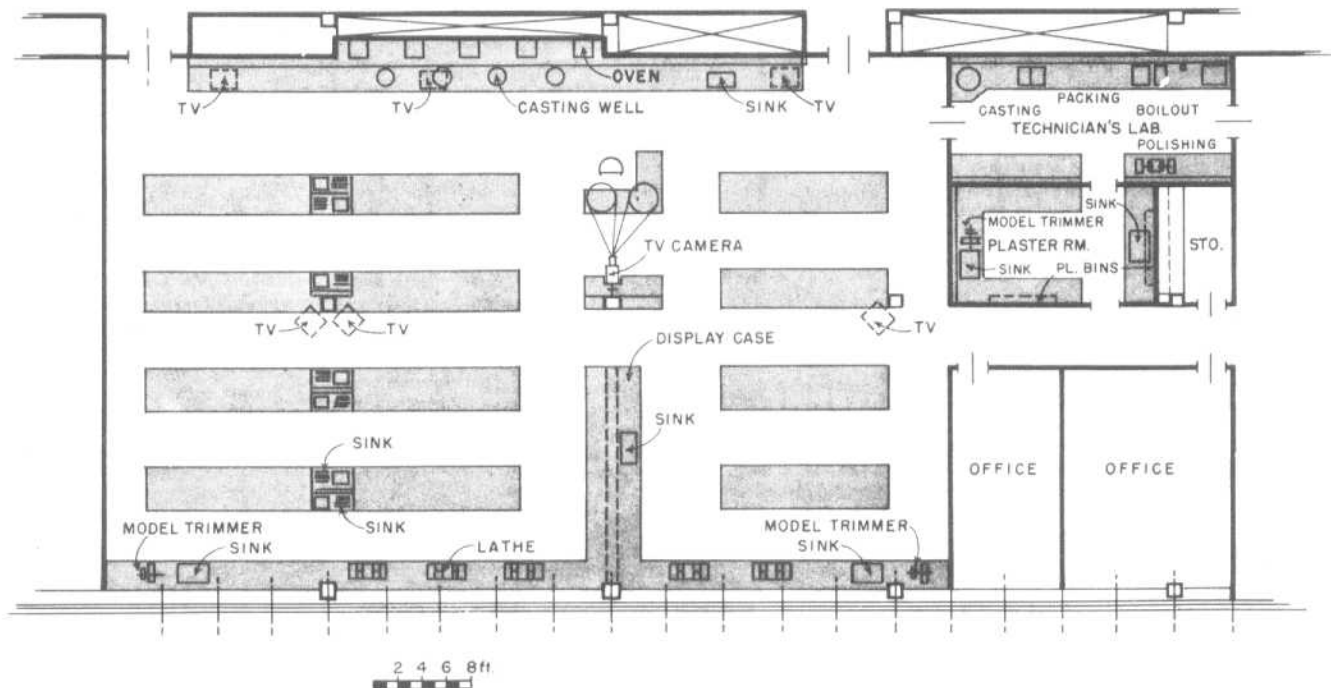

Fig. 8 Preclinical laboratory of 96 student positions utilizing closed-circuit television for demonstrations.

clinical laboratory is actually a multidiscipline laboratory, for all the preclinical dental science courses are taught here: the instructors of the several subjects take over the laboratory in turn while the students remain in their assigned places.

Seating. In the arrangement most common to preclinical laboratories, students sit on each side of a bench, their backs to those of students at the next row of benches. The aisles separating the rows are at least 4 ft 6 in. wide, so that the instructor may move easily between the benches as he inspects the students' work.

In some of the newer laboratories, benches are arranged so that all students face in one direction—usually toward the instructor's podium. The aisles between benches—a 3 ft minimum is satisfactory—are not as wide as those required for back-to-back seating. On the other hand, back-to-back seating is economical. It conserves floor space and reduces the cost of bench work and utilities.

In either of the two seating plans, high or low benches can be used, but the low bench—32 in. in height—will perhaps be the more satisfactory. With low benches, a standard adjustable typing chair on casters can be used and is less costly than the laboratory stool. All benches should be equipped with gas, air, and duplex electrical receptacles. Each student station at the bench should be at least 3 ft wide, and 3 ft 6 in. is actually more satisfactory. If the latter figure is used, an over-all allowance of 38 sq ft per student position will provide adequately for the teaching facilities.

Every preclinical technic laboratory should provide the instructor with a table or desk, equipped with gas, air, and electricity for demonstration purposes. In large classes which require more than one instructor, each should be allotted desk space.

Ancillary Facilities. To reduce the tracking of plaster from the laboratory into the public corridors, the processing room, which is used

for pouring wax forms, molds, impressions, and flasks for denture processing, can be located adjacent to the preclinical technic laboratory. Also nearby should be a small storeroom.

ETV in the Preclinical Laboratory Figure 8 shows a preclinical dental technic laboratory of 96 student positions together with an adjoining processing room. Demonstrations within the laboratory are given with closed-circuit television. There are 16 students per monitor. The monitors are also coupled to the television studio of the school.

This layout is also adaptable to the monitoring of students' work by closed-circuit television. In such a system, the picture is relayed to the console at the demonstration position.

While the principal medium of demonstration is ETV, facilities for chalk talks and for projection of motion pictures or slides are provided. Display cases, some of which permit viewing from both sides, should be provided for models and examples of student work. The laboratory shown has the equipment used in common by students, such as lathes, model trimmers, sinks, ovens and casting machines, located at the perimeter walls.

THE CLINICS: FUNCTION AND OPERATION
